No. 3894.] LONDON, SATURDAY, APRIL 16, 1898. [Pp. 120+40.

CONTENTS.

HUNTERIAN LECTURES (Abstract of the) on the Surgery of the Kidney. Delivered before the Royal College of Surgeons of England on March 21st, 23rd, & 25th, 1898, by HENRY MORRIS, F.R.C.S. Eng., Surgeon to the Middlesex Hospital.—Lecture I. 1037

A LECTURE on Moveable Kidney and its Treatment. Delivered at the West London Hospital by LEONARD A. BIDWELL, F.R.C.S.Eng., Senior Assistant Surgeon to the West London Hospital... 1041

ORIGINAL ARTICLES.

A Case in which the Cæcum and the Ascending and Transverse Colon were Removed for Malignant Disease; Recovery. By R. LAWFORD KNAGGS, M.C. Cantab., F.R.C.S.Eng., Assistant Surgeon to the Leeds General Infirmary.—*(Illustrated)* 1042

On Pneumonia following Injuries to the Chest and the Possible Occurrence of Pulmonary Tuberculosis as a Sequence to Trauma. By THOMAS HARRIS, M.D., F.R.C.P.Lond., Physician to the Manchester Royal Infirmary and Lecturer on Diseases of the Respiratory Organs in Owens College.—*(Illustrated)* 1045

Vitality: An Appeal, an Apology, and a Challenge addressed to Brother Practitioners. By LIONEL S. BEALE 1048

Notes on a Case of Porro-Tait's Operation. By ALBERT E. MORISON, M.B., F.R.C.S. Edin., Honorary Surgeon to the Hartlepools Hospital 1050

Uterus Unicornis. By HEYWOOD SMITH, M.A., M.D. Oxon. 1051

A Case of Extensive Extravasations of Blood in various parts of the Body occurring in an Anæmic Woman. By EDWARD JOSEPH BLACKETT, M.R.C.S. Eng., L.R.C.P. Lond. 1052

CLINICAL NOTES:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A Symptom following Angina Pectoris. By ALBERT S. WORTON, M.B., C.M.Glasg. 1053

Parotitis from Obstruction of Stensen's Duct. By R. HILL BROWN, M.B., C.M.Edin. ... 1053

A Case of Dead Twin Retained to Full Term. By WALTER C. HEARDEN, M.R.C.S. Eng., L.R.C.P. 1053

A MIRROR OF HOSPITAL PRACTICE.

TEDDINGTON COTTAGE HOSPITAL: A Case of Cæsarean Section. (Under the care of Mr. R. A. Clarke) 1053

SHEFFIELD ROYAL HOSPITAL: A Case of Pulmonary Abscess Successfully Drained. (Under the care of Dr. Duncan Burgess and Mr. Sinclair White) 1054

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY: Immunity from Cobra Poison.—Exhibition of Specimens 1055

HARVEIAN SOCIETY: The Treatment of Caries of the Spine 1056

OBSTETRICAL SOCIETY: The Menstruation and Ovulation of Monkeys and of the Human Female 1056

WEST KENT MEDICO-CHIRURGICAL SOCIETY: The Use and Abuse of Mydriatics.—Morphia in Cardiac Diseases 1057

ROYAL ACADEMY OF MEDICINE IN IRELAND: Clinical Report of the Rotunda Hospital 1057

ULSTER MEDICAL SOCIETY: Management of Labour.—Life Insurance 1058

REVIEWS AND NOTICES OF BOOKS.

Memory and its Cultivation. By F. W. Edridge-Green, M.D.Durh., F.R.C.S.Eng. ... 1058

The Royal London Ophthalmic Hospital Reports. Edited by William Lang, F.R.C.S. Eng. 1059

A Manual of Botany. By J. Reynolds Green, Sc.D., F.R.S. F.L.S. Vol. II. 1059

Analytical Key to the Natural Orders of Flowering Plants. By Franz Thonner 1059

The Principles of Bacteriology. By A. C. Abbott, M.D. 1059

Il Piede e la sua Razionale Calzatura. By Dr. F. Brunelli 1060

Archives de Physiologie. Publiées par MM. Bouchard, Chauveau, et Marcy 1060

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.

Vejos and Fluid Vejos.—Aerated Waters.—Voline—Health Foods.—"Perfected" Cod-Liver Oil.—Bensolyptus.—Special Blend Old Scotch Whisky 1060

NEW INVENTIONS.

A New Clinical Thermometer 1061

LEADING ARTICLES.

THE GENERAL MEDICAL COUNCIL AND THE MIDWIVES QUESTION 1062

ABSTRACT OF

The Hunterian Lectures

ON

THE SURGERY OF THE KIDNEY.

Delivered before the Royal College of Surgeons of England on March 21st, 23rd, and 25th, 1898,

BY HENRY MORRIS, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE I.

Delivered on March 21st.

THE ORIGIN AND PROGRESS OF RENAL SURGERY AND THE CONSERVATIVE TENDENCY OF ITS RECENT DEVELOPMENT.

MR. PRESIDENT AND GENTLEMEN, — In selecting the subject for the lectures which by the grace of the Council I am about to deliver I was influenced by the fact that "renal surgery," though it has attracted a good deal of attention amongst surgeons during the last twenty years, has not yet received the general recognition by the profession at large to which it is entitled, nor has it hitherto been the theme of any Hunterian professor. I propose in this lecture to describe briefly the origin, and then to trace the progress, of this quite modern branch of surgery.

History.—In the sixteenth, seventeenth, and eighteenth centuries the practicability of nephrotomy was repeatedly discussed by Camerarius and François Rousset in 1581, by Shenck in 1584, and other early writers, and in 1829 it found a very ardent supporter in P. N. Gerdy.[1] As regards nephrectomy, various physiological experiments upon animals were undertaken by Zambeccarius[2] about the year 1670, and Roonhuyzen[3] in 1672, to show that life could be well maintained after removing one of the kidneys. The cases of the archer of Meudon, of the British consul at Venice, and others, which had found their way into surgical literature, may be dismissed in the words of M. Hevin,[4] who wrote in the year 1757: "It is very doubtful, if not absolutely improbable, that cutting into the kidney had ever been practised without the operation having been determined by an abscess swelling or by a fistula due to renal abscess which had broken and discharged in the lumbar region." None of these cases had any influence in encouraging surgeons to operate upon the kidney and no surgical treatment for any kind of renal disease was systematically employed until the second half of the present century had well advanced.

Nephrectomy.—The dawn of renal surgery admittedly dates from Aug. 2nd, 1869, when Gustav Simon, of Heidelberg, successfully removed by the lumbar method the kidney of a woman who had an ureteral fistula opening upon the abdominal wall above the pubes and following on ovariotomy done one and a half years before. Simon performed his operation in face of the pronouncement long before made by Rayer that it was "madness to dream of extirpating a kidney in the human subject." He no doubt was aware of the experimental results of Prévost and Dumas (1823), of Claude Bernard, Rayer, Meissner, Shephard, all of whom established the fact that animals could live with only one kidney. For himself, he compared the results of 15 hysterectomies with 15 nephrectomies practised on animals and was satisfied that there was no more danger from a surgical point of view in the one operation than in the other and at the same time he convinced himself that the physiological changes effected by the kidneys could be amply performed by one after the ablation of the other organ. Rather more than a year after Simon's case Gilmore in America followed (December, 1870) with a very successful nephrectomy for a painful shrunken fibrous kidney in a woman, five months pregnant, who recovered without a miscarriage. In England the first nephrectomy was performed by Arthur E. Durham on May 14th, 1872. The next was by Jessop and the third by Barker. Barker, who had made himself thoroughly familiar with Simon's work, read two important papers before the Royal Medical and Chirurgical Society; one in March, 1880, and the other in April, 1881. He therein tabulated all the nephrectomies done up to those dates and thus brought the whole subject of extirpation of the kidney before the notice of British surgeons, who till then, for the most part, were quite unfamiliar with it. In France, where the earliest and most ardent advocates of nephrotomy had lived, nephrectomy was for several years either neglected or opposed. It was not until May 20th, 1880, nearly eleven years after Simon's successful initiative, that M. Léon Le Fort practised the first nephrectomy done in France.

Nephrotomy is the operation which had received most consideration in past times, especially in its bearing on the treatment of renal calculous disorders; but it was not in all probability ever systematically put into practice until 1870. Previously to 1870 fluid swellings, believed to be of the kidney, had been punctured and opened by the thermo-cautery and perinephric abscesses had been incised through the loin. On April 27th, 1869, three months before Gustav Simon's first nephrectomy, a paper was read by Thomas Smith describing a method for exposing the kidney through the loin. This he advocated for diagnostic purposes and for the extraction of a calculus if of suitable size and shape and capable of removal through the renal pelvis, but not if fixed in the substance of the kidney or if its removal entailed cutting into the normal secreting structure. Though the author had no actual case of his own to record and advocated nothing more than had been recommended on several occasions during the two preceding centuries, there can, I think, be little doubt that his paper, coming when it did, influenced the minds of surgeons to a degree which previous similar suggestions had failed to do. In July of the same year (1869) Annandale, and in January, 1870, Spencer Wells[5] wrote in favour of nephrotomy in some cases of renal calculus. These articles, together with Simon's success, were all factors leading up to the application of nephrotomy to a class of case for which no one had as yet, so far as our absolute knowledge goes, suggested it—namely, for cases of renal calculus in a kidney otherwise normal. In 1870 Bryant performed nephrotomy for tuberculous pyonephrosis, but at too late a stage to save his patient; and in the same year Gunn and Durham each cut down *upon* the kidney; and Lente and Barbour each cut *into* the kidney with the object of removing calculi, but none were found. All four patients recovered. During the next ten years, 1870–1880, nephrotomy was done in some half-dozen cases (according to Dickinson's tables), in each of which there was a large pyonephrosis, more or less pointing at the loin; and in four of these calculi were extracted.

Nephrolithotomy.—No further advance, however, was made in the operative treatment of renal disorders till Feb. 11th, 1880, when I successfully removed a mulberry calculus weighing 31 gr. from the undistended and, to the naked eye, quite normal kidney of a young woman. The kidney was exposed through an oblique lumbar incision and the stone reached and removed through the renal parenchyma. This case demonstrated for the first time that a stone could be removed safely by cutting freely upon it through a thick layer of renal tissue. It thus became the starting point of both the development and the conservatism of renal surgery which I am persuaded will become more and more conservative in the future. The second nephrolithotomy was performed in August, 1881, by the late Mr. Marcus Beck; others more or less quickly followed and in the list of my operations for removal of renal calculus by nephrolithotomy I am able to show 34 operations with recovery in 33 and death in 1. These results disprove the supposed dangers of nephrolithotomy and show the invalidity of the objections which in all previous times had been urged against the proposal to operate upon a kidney not already converted into a mere abscess sac.

Nephropexy.—Fourten months after the first nephrolithotomy Hahn of Berlin introduced an operation at first called nephrorrhaphy and afterwards by the French writers

nephropexy for fixing moveable kidneys. This consisted in an incision alongside the sacro-lumbalis muscle from the twelfth rib to the crest of the ilium; the quadratus lumborum was cut and the fibro-fatty capsule of the kidney opened along the outer border of the kidney; the fibro-fatty capsule was separated to some extent from the kidney and dragged forcibly backwards into the wound along with it. By means of six or eight catgut sutures this capsule was stitched into the wound and the wound itself plugged with carbolic gauze. In his account, published in July, 1881, Hahn describes two cases thus operated upon by himself in April of that year. The patients were both women and recovered in four weeks with the kidneys as securely in their attached position as immediately after operation. This was an important advance because it at once had the effect of putting a stop to nephrectomy for moveable kidney which had been recommended and practised by Martin of Berlin in 1878. I never felt confidence in this mode of fixation and preferred to attach the kidney itself to the cut edges of the transversalis fascia and the aponeurosis of the transversalis muscle by means of three sutures dipping deeply into the posterior surface of the organ and running for from three-quarters of an inch to an inch in its substance. I have used various materials for suture—stout catgut, kangaroo tendon, and silk, but now always employ silk. The results obtained have in most of the cases been perfectly satisfactory, and I see from time to time patients upon whom I operated nine or ten years ago with their kidneys as firmly fixed as can be desired and who have been quite free from their former symptoms ever since the operation. Tuffier recommends partial decortication of the kidney and the suturing of the tunica propria to the edges of the parietal wound. This done he thinks the parenchyma does not fail to attach itself firmly to the neighbouring tissue by the whole of the exposed area. A fourth method has more recently been suggested by Vulliet of Geneva and was first tried by his friend Poullet of Lyons. It consists in making use of a long slender slip of the tendon of the erector spinæ of the patient as the means of fixation of the kidney. I prefer Vulliet's method to Tuffier's, but neither is so simple, or so rapidly done as, or more efficacious than my own.

Partial excisions.—Another most important advance in the conservatism of the surgery of the kidney is the excision of diseased portions of the organ in place of nephrectomy. This step was a natural result of the establishment of nephrolithotomy as a sound surgical procedure. The fear of uncontrollable bleeding during the operation and the doubts as to the healing power of a kidney cut into or otherwise wounded being once removed, the attempt to save the greater part of the organ when only a small portion was diseased or injured was bound to be made. Tuffier's experiments on animals in 1888 and Barth's histological researches supply ample proofs of the healing power of the kidney and of the process by which this healing is accomplished, even after extirpation of considerable portions. Dr. Paoli[6] of Perugia performed extra-peritoneal operations for resection of the kidney upon 25 dogs, cats, and rabbits with perfect recovery and published his results in 1890. But such experiments were not required to convince us that wounds of the human kidney readily heal. In 1883 and 1884 I collected for my work on diseases of the kidney a number of cases proving the cicatrising capacity of the human kidney after incised, punctured, lacerated, and also gunshot wounds. Up to the present time partial excision or resection has been very rarely performed. An excellent epitome of the work hitherto done in this direction is contained in a paper read before the British Medical Association at Carlisle in 1896 by Oscar Bloch of Copenhagen. He therein reports a case in which he removed, in September, 1895, half the kidney affected by a new growth and gives abstracts of ten cases which he collected from German and French sources.

My own experience of resection commenced in November, 1890, when in drawing out a kidney of a young man, aged twenty-four years, which I was exploring for calculus, several abscesses were seen in the cortex, which I opened, evacuated, and scraped. The kidney was replaced and the loin wound closed, but a week later I had to remove the whole kidney on account of acute general pyonephritis. The man quite recovered after a long convalescence and is well and leading an active life to-day. In April, 1892,[7] I scraped out six tuberculous masses in the kidney of a man, aged twenty-eight years, which I was exploring for calculus. An excellent recovery followed. In a third case I found three areas of grouped miliary tubercles at different points of the kidney. I removed them by excising three wedges of the renal parenchyma and in so doing opened up the calyces. The patient made a rapid recovery and left the home without a sinus on Jan. 16th, 1895. In March, 1897, two years and two months afterwards, the patient was quite well. In three other cases I have done similar successful operations on women. Partial resections are capable of a wider application than has yet been given to the operation, especially in the case of tumours taking origin from the renal capsule, and those which, though originating in the perinephric tissue, grow into, and partially destroy, the kidney itself. Bardenheuer and, in this country, E. Owen and Keetley, acting on the same conservative principle, have treated cases of accidental injuries of the kidneys by taking away a portion and leaving the bulk of the organ.

Operations on the ureter.—Operations upon the ureter are an advance of the last few years, but not many have been recorded up to the present time. They are of very considerable importance because of the influence they are having, and are destined to have, upon renal surgery generally. Ureterotomy has been employed in the treatment of hydronephrosis, calculus, and calculous anuria. Ureterectomy will improve the results of operations for advanced tuberculous disease and also of those performed for calculous pyonephrosis complicated with ureteritis. Ureteral anastomosis and other plastic operations on the ureter will save many kidneys which would formerly have been nephrectomised on account of hydronephrosis, fistulæ, and surgical injuries of the ureter. It is of interest to note that ureterotomy, like nephrotomy and nephrolithotomy, was suggested many years before it was put into practice. The first allusion to it which I have met with is in Velpeau's "Surgery" (edition 1851, p. 1021). In 1856 a remarkable series of articles was published by Dr. C. Gigon of Angoulême[8] in which he suggested opening the ureter with the object of establishing an artificial passage for the escape of the urine in a case of calculous anuria.

Ureterotomy for calculus.—In 1879 Thomas Addis Emmet of New York (in the edition of his work on the "Principles and Practice of Gynæcology") stated that in three cases he had met with stones obstructing the vesical end of the ureters. In one he removed the stone through the bladder by means of curette forceps after opening the bladder. In the second case he removed a stone weighing 98 grains by cutting upon it through the vaginal wall without having opened either the bladder or the peritoneum and he closed the opening with interrupted sutures. His third case does not seem to have been operated upon. In 1882 Bardenheuer performed ureterotomy for calculous anuria, removed four stones, one of which was impacted in the upper end of the ureter, and closed the ureteral incision by sutures. In Bardenheuer's case the urine did not find its way subsequently into the bladder, so he divided the ureter and established a lumbar ureteral fistula. In 1885 Cullingworth removed a calculus from the lower end of the ureter of a woman by abdominal section. In and since 1887 ureterotomy was performed for the extraction of calculi impacted in different parts of the ureter by means of a retro-peritoneal operation in the lumbar or inguino-lumbar region by Godlee in 1887, by Kirkham and Torrey in 1889, by Twynam in 1890 and by several other surgeons since.

Ureterotomy for stricture and valvular obstruction.—Another application of ureterotomy is in cases of ureteral stenosis. Simon in 1876 was the first to give theoretical directions for this operation. I do not know that he ever performed it. Trendelenburg in 1890 was, I believe, the first to make the attempt. In 1892 Fenger of Chicago performed the first successful ureterotomy for a valvular stricture of the ureter; on Nov. 26th of the same year he operated upon a man, aged forty-seven years, for intermittent hydronephrosis of twenty years' duration due to a stricture of the ureter close to its junction with the infundibulum. The kidney and upper end of the ureter were exposed through a lumbar incision. The upper end of the ureter for half an inch was found embedded in cicatricial tissue; below this the ureter was normal. A longitudinal incision, a centimetre long, was made into the ureter just below the cicatrix and the

[8] L'Union Médicale, Feb. 14th, 18th, and 21st, 1856.

strictured part of the tube was divided from below upwards to the renal pelvis. The ends of the incision in the ureter were stitched together by the Heineke-Mikulicz manner for closing the pylorus after division for stenosis. I have recently done a similar operation on a female patient, aged twenty-nine years, who for four or five months has had intermittent periods of aching in the right kidney, which was very moveable, associated with very frequent micturition. At these times the urine became very thick and offensive and at other times there was pus in small but distinct quantity in the urine. There was marked tenderness on bimanual examination so that renal calculus was suspected. Through a lumbar incision the upper end of the kidney was seen to be firmly bound down by tough fibrous adhesions. The pelvis of the kidney was distended to the size of a tennis ball and the ureter was so constricted as barely to admit the smallest ureteral catheter. The kidney was incised along the convex border and thoroughly explored for stone. None was present, but the calyces were found to be slightly sacculated. The constricted orifice of the ureter was longitudinally divided upon the catheter, which was passed from a small opening in the infundibulum through the stricture to the bladder, and the ends of the incision were drawn together by the Heineke-Mikulicz method by means of two fine silk sutures passed after the manner of Lembert. Nephropexy was then performed by Vulliet's plan. The wound healed entirely by first intention and there has been no return since of the symptoms which led to the operation.

Resection of the ureter.—Resection of the ureter is the operation whereby an inch or two, or a little more, of the duct is removed and the ureter is united to the infundibulum, or the divided ends of the ureter to one another, as the case may be, so as to restore the continuity of the conduit. It was first proposed by Marcel Beaudoin in 1891 and first performed by Küster in May, 1891. Küster reported his case at the Congress of Surgeons held in Berlin in 1892.[9] The patient was a boy, aged thirteen years, with only a single kidney, who for two years had passed *all* his urine through a fistula, following lumbar nephrotomy, for hydronephrosis. The cause of the hydronephrosis was a very slight stricture of the ureter near the renal pelvis. The strictured part of the ureter was excised and the cutend of the ureter was sutured to the renal pelvis. By the end of four months from the date of this operation all the urine was passed naturally and the fistula was quite closed. Cramer of Cologne followed Küster's lead in a case of hydronephrosis in 1893 and again on operating on a case of pyonephrosis in 1894.[10] Weller Van Hook in 1893 published a case in which he practised Küster's operation, but immediately he had completed it he found an obstruction in the ureter lower down and therefore removed the kidney. In 1897 I operated upon a female patient, aged fifty-six years, for painful intermittent hydronephrosis and found the ureter running obliquely in the wall of the distended renal pelvis. In this case I first laid the ureter and renal pelvis freely open into one another and stitched the divided edges of the ureter to those of the renal pelvis. The result was not satisfactory so I excised three-quarters of an inch of the ureter, closed the greater part of the incision in the renal pelvis and then sutured the ureter to the lowest part of the infundibulum as Küster had done. Again the result did not satisfy me because of the small calibre and extreme tenuity of the ureter, so to avoid a fistula and a long convalescence on the one hand, or stenosis of the ureter at the site of operation and a subsequent nephrectomy on the other hand, I removed the kidney there and then. The operations for resection of the ureter for hydronephrosis (or pyonephrosis) above quoted show that the aim in our treatment of hydronephrosis ought to be conservative. Before actually proceeding to resect the ureter for stricture or a valve the surgeon should not fail to ascertain whether there is a clear channel in the ureter below the stricture or valve to be divided, otherwise he may find that the operation is useless when completed.

Ureterectomy.—By resection of the ureter is meant the cutting out of a short piece of the duct, not exceeding from two to two and a half inches, with the object of restoring it to its proper capacity as a conduit of the urine to the bladder. It is a truly conservative operation. More extensive excisions of the ureter, and even the removal of the whole length of the duct, have of late years been occasionally practised and with most beneficial results; but, like nephrectomy, such operations are, of course, not of a conservative nature. Ureterectomy, partial or complete, has been performed for tuberculosis, suppuration in the dilated ureter, hydrops of the ureter, and for the cure of suppurating lumbar fistula due to the presence of a diseased ureter, after nephrectomy had been done. The operation may be either primary or secondary. It is primary when the ureter is removed simultaneously with the kidney; secondary when the excision of the ureter follows the removal of the kidney as a distinct subsequent operation. Two different routes have been followed in the complete removal—namely, the transperitoneal and the extra-peritoneal; but the latter gives so complete and satisfactory a field for the necessary manipulations and has other anatomical and surgical advantages that it is not probable the transperitoneal method will find any followers. Several different routes have been taken or suggested for the partial ureterectomies affecting the lower part of the duct. In the male the inguinal extra-peritoneal route—i.e., through an incision the same as the lower part of the incision for complete extra-peritoneal ureterectomy—is the best, but in the female the para-sacral, or a combination of the inguinal and vaginal methods as practised by Kelly, has advantages over the others.

Wounds of the ureter.—Another way in which great advance has been made in renal surgery in the conservative direction is in the management of wounds of the ureter inflicted accidentally during the course of such operations as ovariotomy, abdominal and vaginal hysterectomy, and the removal of suppurating Fallopian tubes and ovaries. The ureter has also been wounded in at least one instance during the course of an operation on the pelvis by the method known as Kraske's. For these injuries nephrectomy had hitherto been performed and in many instances of the kind healthy kidneys have been removed. This is a discomforting reflection; and not unnaturally as soon as accidental surgical wounds became of pretty frequent occurrence there were surgeons who set themselves to devise some alternative for nephrectomy. Numerous experiments on animals were made by Tuffier in France, Boari and Pozzi, Gusserow and Pawlik, Alfonso Poggi of Bologna, Van Hook, Byron Robinson, Bovée, and others in America, and a great variety of methods have been devised for remedying the injury without sacrificing the kidney. They may be grouped into two distinct classes—viz., (1) those designed to restore the continuity of the ureter; and, failing this, (2) those for anastomosing the cut end of the ureter with the external surface, with the intestine, or with the bladder. If the ureter should be wounded during an abdominal or vaginal operation and the injury is detected by the surgeon at the time, one or the other of these operations ought to be, if possible, immediately practised. Such a complication can only be suitably grappled with by one familiar with the varieties and possibilities of surgery which recent experiments and scattered cases have brought to light. It is very desirable, therefore, that surgeons and gynæcologists who are exposed to the risks of injuring the ureter should have a fair working knowledge of the remedies, short of sacrificing the kidney, which are available.

Uretero-ureteral anastomosis.—Schopf,[11] in 1886, was the first who practised uretero-ureteral anastomosis in the human subject. He employed the end-to-end method. In 1887 Alfonso Poggi[12] of Bologna invaginated the upper into the lower end of the divided ureter. This is the end-in-end method. Six years after Poggi's experiments Van Hook[13] of Chicago published a description of his experiments on dogs of the lateral implantation of the upper portion of the ureter into an opening in the side of the lower portion. Van Hook points out an important fact in connexion with these ureteral operations—namely, "the lumen of the tube can be enormously increased by stretching without prejudice to the integrity of its walls." When the upper portion of the divided ureter is very much distended and has to be puckered to get it into the lower portion, which may be only half its size or even less, three sutures instead of one might be advantageously employed as was done by Emmet.[14] Finally, Bovée in 1895 adopted a plan which consists in suturing the cut ends together obliquely. He published

[14] Bache Emmet: The American Journal of Obstetrics, April, 1895.

an account of it in January, 1897.[15] He performed his operation on a woman, aged thirty-six years, whose right ureter he unintentionally included in a ligature and then divided when excising the right ovary and tube for an abscess. Of the 12 cases of the application of these methods to ureters injured during surgical operations, in 11 the section of the duct was complete and in one incomplete (Pawlik's case). To this case of incomplete section of the ureter I may add one of my own in which the dilated ureter was three parts divided. In both of them the mode of treatment was practically the same—viz., closure of the wound by very fine silk sutures passed in the fashion of Lembert and covering the injured ureter with the peritoneum. For transverse wounds which do not completely divide the ureter but involve one-third or more of its circumference Van Hook has proposed the following operation: "Make two longitudinal incisions in the ureter with a pair of small scissors, beginning at the middle of the wound to be closed, and suture longitudinally"—i.e., in the direction of the long axis of the tube—"with the object of producing a very wide instead of a very contracted lumen." By this method cicatricial contraction cannot obstruct the flow of urine. When the wound involves the peritoneal aspect of the duct—as it necessarily does in accidents during abdominal operations—he advises that the union should be protected by surrounding it with a fold of peritoneum. A mere puncture or a small wound which merely gapes slightly may be securely closed by one or more Lembert sutures and a covering of peritoneum.

The classes of cases in which uretero-ureteral anastomosis is applicable are the following. To restore the continuity of the duct (1) after accidental section during abdominal operations; (2) after unintentional resection of a short length of the duct during abdominal operations (two or even three inches may be removed and the ends afterwards brought together without undue tension on the union); (3) after resection of a portion of the ureter for stricture, ulceration, sloughing around a calculus, or any other condition which, if not removed, would terminate in stenosis; and (4) after rupture and other injuries from external violence—as soon as the case is diagnosed when intra-peritoneal and before suppuration or sloughing occurs when retro-peritoneal.

Ureteral grafting.—An immense amount of labour and ingenuity has been given to devising methods (1) for the cure of ureteral fistula and (2) for the prevention of ureteral fistula and of nephrectomy in cases in which the ureter has suffered a loss of substance too great to permit of uretero-ureteral anastomosis. Very numerous have been the experiments to test the feasibility of grafting the cut end of the ureter (1) into the bladder; (2) into the rectum; (3) into other parts of the small and large intestines; and (4) on to the skin in the loin. Various other ingenious plans have been proposed as substitutes for nephrectomy whereby the urine is conducted to the bladder even after parts of the ureter, too great to permit of uretero-ureteral anastomosis or of bladder-grafting, have been cut away or otherwise destroyed. But the results of actual operations show that grafting into the bladder—uretéro-cysto-néostomie as Bazy has named it—should be always the operation of choice when it can possibly be done. All this industry is the result of the comparative frequency of uretero-vaginal and uretero-uterine fistulæ, especially since the vulgarisation of vaginal hysterectomy. Thus a great many ingenious operations, some of great difficulty and requiring attention to very minute operative details, have been practised or proposed with the object of avoiding nephrectomy. How needful this was must be only too well known to surgeons who have heard or read of such cases as the following. A woman who had undergone vaginal hysterectomy by a distinguished gynæcologist recovered with an uretero-vaginal fistula. The patient was handed over to a distinguished general surgeon to be cured of this fistula. Efforts were made in a most careful manner to ascertain which ureter it was which had been wounded and become entangled in the vaginal cicatrix. These failing to afford definite information the ureter of the suspected kidney was exposed through a lumbar incision and was temporarily ligatured. During this experiment—which was, of course, made under chloroform—no urine escaped by the vagina but a certain amount was withdrawn by catheter from the bladder at the expiration of a given time. The inference was that the ureter temporarily ligatured was the one involved in the vaginal fistula, so the corresponding kidney was there and then excised. Imagine the surgeon's chagrin and the patient's distress the next day when it was discovered that though she had lost a healthy kidney the operation had not cured her of the fistula, for the wrong organ had been removed.

It is impossible for me here to describe the work done or even to name the many workers in this field of experimental and clinical surgery. I can only mention briefly the most satisfactory plastic operations upon the ureter by vesical grafting. They may be classified as follows: (1) invaginating the fistulous aperture itself into the bladder after first incising the vesico-vaginal septum; (2) grafting the ureter into the bladder through the vagina; (3) grafting the ureter into the bladder by an extra-peritoneal route through an incision in the abdominal wall; and (4) grafting the ureter into the bladder by a transperitoneal or intra-peritoneal operation.

Since Simon in 1869 first practised nephrectomy as the remedy for ureteral fistula the operation has been frequently performed for this cause up to the present time. Tuffier in a recently published communication refers to 24 cases which he had collected. But with our present knowledge of the surgery of the ureter nephrectomy for fistula has become in most instances, I do not say in all, an unjustifiable procedure. It ought to be reserved for quite exceptional cases, as, for instance, where the state of the kidney itself is prejudicial to health; or when the surgeon having tried and failed has given up the attempt to cure a troublesome and loathsome fistula by plastic operation. Nephrectomy as a primary operation for surgical injuries of the ureter is quite unjustifiable and as a secondary operation for these injuries it comes under the criticism just made upon it for the treatment of fistula. As a remedy for moveable kidney nephrectomy has come and gone, never, it is hoped, to return. In cases of limited suppuration, of circumscribed tuberculous disease, of innocent growths, and in certain injuries of the kidney, partial excisions are now being performed in place of nephrectomy. In many instances of calculous pyonephroses irrigation of the renal calyces and infundibulum, followed by suture of the kidney, has taken the place of nephrectomy. In hydronephrosis a few laudable attempts have been made, and in a good proportion of them with success, to remove the cause of the obstruction and thus by means of a plastic operation to spare the kidney. In fact, the tendency of the surgery of to-day is to save as much of the kidney tissue as possible consistently with the safety and well-being of the patient. In this very imperfect survey of the origin and progress of renal surgery I hope I have succeeded in showing that whilst its origin was nephrectomy, its progress, especially during the last ten years, has been in the direction of rendering nephrectomy more and more an operation to be avoided.

BEDFORD MEDICAL SOCIETY.—A general meeting of this society was held on March 31st, the President, Mr. M. F. Cock, being in the chair.—The President delivered an address referring especially to the Midwives Registration and Vaccination Bills and medical aid associations.—A discussion on the Midwives Bill followed and a resolution condemning the Bill was unanimously passed.—Dr. Goldsmith introduced a discussion on Post-partum Hæmorrhage with special reference to the Treatment by Compression of the Abdominal Aorta.—Dr. Coombs showed a man with Coloboma of the Iris and Choroid.—Dr. Hartley showed a woman who had suffered from a large Varicose Vein which had become obliterated by an attack of Phlebitis and had entirely disappeared.—Dr. Ross showed sections of Carcinoma of the Mamma and Myeloid Sarcoma of the Femur.

LITERARY INTELLIGENCE.—A new work entitled "The Blood: How to Examine and Diagnose its Diseases," by Mr. Alfred C. Coles, M.D. Edin., with six coloured plates, will be published in a few days by Messrs. J. & A. Churchill. The same firm also announce a fifth edition of Tomes' "Manual of Dental Anatomy" with several new illustrations. This well-known handbook is intended for the dental student qualifying for examination, but to meet the requirements of the student of biology the portion on comparative odontology has been expanded.

A Lecture
ON
MOVEABLE KIDNEY AND ITS TREATMENT.

Delivered at the West London Hospital

BY LEONARD A. BIDWELL, F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE WEST LONDON HOSPITAL.

GENTLEMEN,—Two different forms of moveable kidney are usually described: in the first variety the organ is freely mobile and forms a definite abdominal tumour, the term "floating kidney" being used for this condition; in the second variety the organ can be displaced only to a small extent and the affection is called "dislocated kidney." The symptoms of these two forms vary considerably and it is often found that they are more severe in the cases where the displacement of the kidney is least marked; in some cases of floating kidney the accidental detection of an abdominal tumour has alone drawn attention to the condition.

Moveable kidney was at one time considered to be a rare affection, but some German statistics, made after examination of a large number of patients in several hospitals, show that some degree of mobility of the kidney is present in about 1 in 250 patients, although in a great number of cases the patients do not suffer any inconvenience from this mobility. It is stated that the proportion of males to females affected is 60 to 87, but probably this ratio is much too high, since the condition is extremely rare in males. The right kidney is affected much more frequently than the left and the proportion is stated to be 11 to 1. The symptoms usually complained of are pain of a dragging nature in the loin and considerable tenderness over the kidney. In some cases there may be symptoms resembling those of renal colic, such as pain running down into the groin and into the genitals. This may be accompanied by increased frequency of micturition and sometimes even by alteration in the urine itself. These latter symptoms are met with more frequently in cases of dislocated kidney and are probably due to a kink of the ureter which produces obstruction of that duct. We also find other symptoms in connexion with this condition, such as severe digestive disturbances, especially pain and vomiting, these symptoms being called "gastric crises." In some cases these crises may resemble gall-stone colic and the gall-bladder has more than once been explored for attacks in reality due to floating kidney. Very severe attacks of migraine are also sometimes associated with floating kidney.

Some of these symptoms are due to the presence of a tumour in the abdomen, others to the dragging on adhesions to the duodenum, others to the interference with the flow of urine from the pelvis of the kidney, and others again may be explained by the effects of dragging on the renal plexus. On examining a case of floating kidney we shall find a large tumour in one lumbar region which can be moved in nearly every direction; it can sometimes be pushed over to the opposite side and can always be made to disappear under the ribs. One thing which is specially marked is the large size of the organ and one often hears a floating kidney described as being much enlarged. This enlargement, however, is only apparent, and when the kidney is exposed it will usually be found to be of the normal size; the apparent enlargement is accounted for by the fact that the abdominal parietes are grasped together with the kidney. In some cases no tumour can be detected at one examination, but is easily found at another time; in fact, the kidney seems to become supported for a time, possibly by the pressure of a full colon; in such a case by turning the patient on her face the kidney becomes dislodged and can be felt. In cases of dislocated kidney the organ may be felt by placing one hand under the loin and the other on the front of the abdomen just below the ribs while the patient is lying on her back, the lower end of the kidney will then be felt to slip up from between the fingers of the two hands; on making the patient sit up again the kidney descends and can again be felt.

Several theories have been advanced with regard to the causation of this condition, but at present we are more or less in ignorance. According to some the condition is due to the effects of wearing corsets which push down the liver and consequently the kidney also; its occurrence is also explained by absorption of the renal fat, but this explanation will not hold water, since in the living body the renal fat is semi-fluid. Congestion of the liver is also credited with causing the displacement in much the same way as tight-lacing. Kendal Franks has pointed out that a consideration of the anatomical relations and connexions of the kidney afford the most rational explanation of the condition. Now the anterior surface of the kidney is marked by the impressions of the organs immediately upon it and it has in consequence the shape of a double inclined plane. This shows that there are two forces acting on the kidney, one pressing it upwards and backwards and the other downwards and backwards. Franks therefore suggests that the kidney is kept in its proper position by the direct pressure backwards resulting from the united action of these two forces. On the right side the kidney is pressed on by the liver above and by the ascending colon below, while on the left side the stomach and the spleen exert pressure above and the descending colon below. Now in order to lose this support some forcible dislocation must occur. This will occur after an injury, such as a fall on the feet, a blow or a squeeze in the loin; it may also be caused by allowing the patient to sit up too soon after parturition. The occurrence of the so-called gastric crises associated with moveable kidney are explained by the connexions which exist between the kidney and the duodenum; consequently any traction on the latter structure by the descent of the kidney would be liable to cause kinking of the duodenum with consequent obstruction to the passage of food from the stomach. In support of this view it is pointed out that the gastric symptoms are not met with when the trouble is on the left side. On this side, however, the descent of the kidney may cause a kink in the splenic flexure of the colon by traction and intractable constipation may result.

With regard to the consequences of moveable kidney if left untreated the most important are the effects of kinking of the ureter producing hydronephrosis and atrophy of the kidney. Apart from this the patient's life may become almost unbearable either from continual pain, from frequent gastric crises, from uncontrollable irritability of the bladder, or from bowel trouble. In either of such cases some treatment is absolutely necessary.

TREATMENT.

The necessity for active treatment will of course depend upon the severity of the symptoms and also upon the condition of the kidney—i.e., whether floating or dislocated. In the former case, where little is complained of except the presence of a tumour, the application of a properly-fitting belt or truss will probably be all that is required. Unfortunately it is often very difficult to get a belt which is comfortable and patients sometimes find that wearing a belt is worse than the disease; this is especially the case when the kidney is tender to the touch. Some surgeons prefer a truss with a pad which presses the kidney up under the ribs. This is undoubtedly a good appliance when it can be borne.

In cases of floating kidney where neither a belt nor a truss can be worn, and in practically all cases of dislocated kidney, the question of operative interference must be considered. Two operations have been proposed—namely, nephrectomy and nephrorraphy. The first-named, however, is unnecessary and should not be undertaken except in a case of floating kidney with a distinct meso-nephron, in which the whole of the kidney substance has been destroyed by long-continued hydronephrosis. In all other cases the operation of nephrorraphy should be performed. Many different ways of performing this operation have been devised, but since the kidney is normally situated under cover of the ribs these methods in which the organ is attached below the last rib are not to be recommended. Among the various methods I may mention: (1) that where the kidney is exposed and the perirenal fat is freely disturbed, no stitches being employed but the wound being plugged to excite adhesions; (2) that where the kidney is attached to the lumbar wound by stitches which are passed through the kidney capsule and out of the skin, and which are withdrawn at the end of fourteen days; (3) that where the capsule is attached by means of buried silk or tendon sutures to the lumbar fascia (these are left in permanently); (4) that where the buried sutures are made to penetrate the kidney substance;

(5) that where the kidney is sutured to the last rib; and (6) that where the kidney is run up and fixed under the ribs by means of one of the tendons of the longissimus dorsi muscle (Vulliett's method). Besides these methods in which the kidney is exposed by a lumbar incision the organ may be reached by the transperitoneal route by an incision in the linea semilunaris and the kidney may then be stitched to the last rib. After a trial of all these methods except the last named I am inclined to recommend the method of Vulliett, since it answers most of the requirements of a nephrorraphy; thus the kidney is fixed in its normal position under cover of the ribs, the material used for suturing is unirritating and not quickly absorbed since it is a living tendon, and lastly the peritoneal cavity is not opened. A description of three cases in which this operation was performed will explain the method.

CASE 1.—A woman, aged twenty-two years, was sent to me by Mr. Cox of Watford. She had suffered for two years from severe dragging pain in the right loin in which region a tumour moveable in a direction upwards and downwards could be felt. The symptoms which gave the most trouble were reflex irritability of the bladder causing increased frequency of micturition; there was also severe pain in the back. As this was evidently a case of dislocated kidney and as the patient was very anxious for some relief she was admitted into the West London Hospital and on Aug. 5th, 1897, she was put under ether and an incision 4 in. in length was made just below and parallel to the last rib. After the kidney had been exposed and freed from its connexions a sponge was placed in this wound and the patient was turned more on her face. Another incision 1½ in. in length was then made just to the right of the spine, its lower end being on a level with the first lumbar vertebra; after dividing the deep fascia the tendon of the longissimus dorsi was exposed. A portion of this on the inner side about ¼ in. in width was separated with a scalpel and then a finger was introduced underneath it. On pulling forcibly upon this it gave way at its attachment to the ribs above, providing a strip about 7 in. or 8 in. in length firmly attached below to the spine of the first lumbar vertebra. A probe was then passed from the dorsal into the lumbar wound between the transverse processes of the last and the eleventh dorsal vertebræ; and after incisions had been made in the capsule of the kidney at its upper and lower ends the separated tendon was brought down by means of a probe to the kidney and was passed beneath the whole length of the capsule. The tendon was then threaded again into the probe and passed back into the dorsal wound. On pulling upon it the kidney was made to run up under the ribs and it became firmly fixed in this position. The free end of the tendon was fixed by tying it in a reef knot to another portion of the longissimus dorsi. The lumbar wound was united by two layers of buried silk sutures and both incisions were completely closed without drainage by means of silkworm gut sutures. Both wounds healed by first intention and the patient left the hospital three weeks after the operation. The kidney has not given any further trouble and cannot now be felt.

CASE 2.—A woman, aged thirty years, had suffered from symptoms of floating kidney for ten years. The symptoms had commenced in consequence of a blow on the right side. A tumour could be felt in the right side which was freely moveable and the patient suffered from an incessant dragging and aching pain in the region of the kidney. An appliance had been tried without any benefit. She was admitted into the West London Hospital and on Sept. 28th, 1897, was put under ether and the kidney exposed by a lumbar incision. A distinct meso-nephron was found but the peritoneum was separated without being opened. A dorsal incision was then made and after isolating a portion of the longissimus dorsi and bringing it into the lumbar wound the capsule of the kidney was threaded with it and run up under the ribs in the same way as in the preceding case. The end of the tendon was sewn down in the wound instead of being tied. Both wounds were completely closed without drainage and healed by first intention, the patient leaving the hospital three weeks after the operation.

CASE 3.—A married woman, aged twenty-nine years, had suffered for some years from moveable kidney and at times was completely disabled by the pain. A distinct and freely moveable tumour could be felt. I saw the case with Dr. Berry of Watford and operated with his assistance on Nov. 13th, 1897. The operation was performed in the same way as in the two preceding cases, the only difficulty being that owing to the presence of a definite meso-nephron the peritoneum was opened in exposing the kidney; the rent in the peritoneum was sutured with fine silk and the operation completed in the usual way. There was no trouble from the peritoneal wound and the patient made an excellent recovery. I have recently heard from her medical attendant that she is now free from pain and that the kidney cannot be felt.

In these three cases, two of which were examples of floating kidney and the other of dislocated kidney, the results have been entirely satisfactory; with the other methods of operating my results have not been so good since the kidney could be felt after the operation in all the cases and in one there was a recurrence of the symptoms which necessitated a second operation. This was discouraging and made me hesitate to recommend a nephrorraphy since I could not promise that the condition would not recur. With Vulliett's method, however, I feel that one can offer every prospect of permanent relief and so I should urge the operation even in preference to the application of a belt, since its results are much more satisfactory and the procedure is practically devoid of risk.

A CASE IN WHICH THE CÆCUM AND THE ASCENDING AND TRANSVERSE COLON WERE REMOVED FOR MALIGNANT DISEASE; RECOVERY.

BY R. LAWFORD KNAGGS, M.C. CANTAB., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE LEEDS GENERAL INFIRMARY.

Dr. F. J. SHEPHERD[1] of Montreal has published a list of 13 cases in which large portions of intestine varying from 10 ft. to 31½ in. had been removed by various operators. Apparently these all referred to the small intestine and were instructive from the evidence they afforded that good health and nutrition can be maintained after the removal of considerable proportions of the whole intestinal absorbing surface.

The large intestine does not lend itself so readily to resection as the small one, and, moreover, the cases in which removal of relatively large proportions would be really justifiable are not of frequent occurrence. Mr. Treves, in THE LANCET of Jan. 29th, 1898 (p. 276), has narrated a remarkable case in which he successfully removed the lower portion of the large intestine from the anus as high as the splenic flexure for a congenital condition of rectum which had produced a chronic obstruction, and the following case, in which the bowel resected for malignant disease extended from the termination of the ileum to the splenic flexure, is an additional proof that very extensive portions of the large intestine may be taken away with safety.

A woman, aged thirty-three years, unmarried, was admitted into the Leeds General Infirmary on July 31st, 1897, when she gave the following history. When six years old she had suffered from tuberculous hip disease. Eighteen months ago she began to have pain, which was generally diffused about the abdomen. Six months later attacks of vomiting and diarrhœa were added, but she sought no advice till two months before admission, when pain first became marked upon the right side. A fortnight later a swelling appeared upon that side of the abdomen and grew rapidly. The diarrhœa persisted but medical treatment checked the vomiting. She had lost much flesh during the last month. On examination a large defined tumour was found occupying the right side of the abdomen and extending just beyond the middle line. It moved downwards on respiration. If grasped by both hands movement up or down was very limited, but laterally and to the left it was remarkably free. Though it could be felt bi-manually in the loin it did not project so clearly behind as a kidney tumour usually does. The shape of the mass was an elongated oval, and its consistency varied at different parts, but in the main it was firm and resistant. Usually dull to percussion, there were times when it was resonant in places. Its examination gave no pain and never elicited visible or palpable contractions either in the lump or in other parts of the abdomen. On vaginal examination the swelling appeared to have no

[1] Brit. Med. Jour., Oct. 9th, 1897, p. 967.

connexion with the pelvic viscera. The tongue was slightly furred, the appetite was good, the motions were loose and contained no blood, and the urine was normal. Though the history as given above was very suggestive of an intestinal growth, yet some doubt was thought to exist as to the true nature of the tumour. An exploratory operation was therefore decided upon.

Operation.—On Aug. 12th the patient was anæsthetised and the abdomen was opened by a 6 inch incision over the lump and to the outer side of the right linea semilunaris. The swelling was found to be situated in the large intestine and to be undoubtedly growth. It was as large as a medium-sized melon and much omentum was attached to it. Its connexions appeared so complicated that it was drawn outside the abdomen for investigation. The discovery was then

FIG. 1.

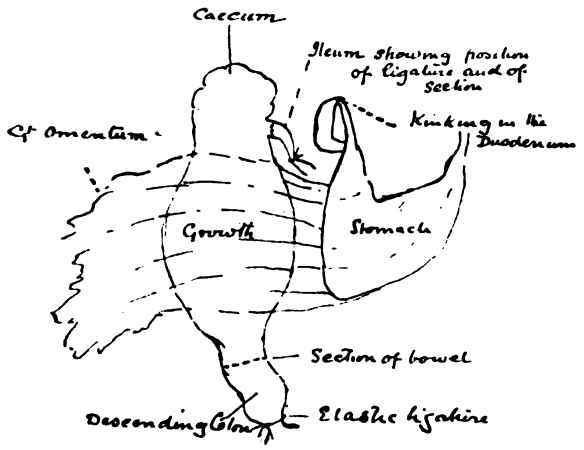

Diagram illustrating the condition met with on commencing operation.

made that the stomach was closely attached to its left side by what proved to be the upper portion of the great omentum, and it was seen that the omentum previously alluded to constituted its lower free portion and that the disease affected the transverse colon. At this point it is perhaps desirable, in order that the description of the operation may be more easily followed, to explain that the normal position of the ascending colon had been completely reversed as a result of this displacement of parts. A finger was now passed above and another below the free edges of the omentum which stretched between the stomach and the colon. They met behind, so this layer of tissue was secured by five or six silk ligatures and divided. A piece of india-rubber tubing was next passed through the mesocolon and tied tightly round the large bowel in the right iliac fossa some four inches below the growth, and the intestine was cut across above the ligature but well clear of the disease. Then the mesocolon was approached with considerable anxiety. It looked and felt like a large roll of fat as big as a flattened fist. It was dealt with from below upwards, portion after portion being ligatured with strong silk and divided. The tumour was now largely detached and hanging outside the wound, and its weight gradually drew down the cæcum from the right hypochondrium. So little of the ascending colon was left uninvolved by the growth that it was quite out of the question to unite two portions of large bowel. The ileum was therefore encircled with another piece of tubing about three inches from the ileo-cæcal valve and was divided close to its entrance into the large intestine. The remaining strands of ascending meso-colon and (?) mesentery were now ligatured and divided with as much consideration for the vitality of the cut end of the ileum as the unusual condition of parts permitted and the growth was removed. In the thick mass of the mesocolon many glands had been felt and when it was divided some were seen, but it was doubtful if they were diseased and it was not thought wise, by attempting to remove them, to enter upon a proceeding which could hardly be thorough and would add largely to the risks which the patient already had to face. The cut ends of the ileum and colon were now united by a Murphy's button. There was considerable strain upon the small bowel and a supporting suture tore through as it was being tightened, so reliance had to be placed upon the button alone. Lastly, the protecting sponges were drawn from the abdomen and iodoform gauze was packed down over the surface of the junction and brought out at the upper angle of the wound and the lower part of the incision was closed in layers. A dry dressing was applied. The operation lasted an hour and the patient was less seriously affected than I had expected, though one or two subcutaneous injections of brandy and strychnia were given towards the end.

The after-progress was not quite uneventful. For a few days there were a certain amount of vomiting and also hiccough which at first was very troublesome. Both symptoms disappeared after the bowels had been freely opened on the fifth day. Rectal feeding was kept up for several days but fluid nourishment by the mouth was commenced the day after the operation. For the first few days the stomach was seen in active movement forming a marked swelling below the thin parietes and later the small intestines in their peristaltic movements produced a lumpy surface of the now flattened abdomen. These movements were never painful and as the abdominal wall became fatter they were gradually lost sight of. The removal of the original gauze packing was attempted on the fifth day but its deeper portion stuck and did not finally separate till two days later. Within the next twenty-four hours fæces appeared in the discharge and for some days a large quantity escaped, but after lasting a week the fæcal fistula closed and never gave any more trouble. On the seventeenth day several ligatures and some sloughy tissue came away, and from that time the granulating track gradually diminished till on the twenty-seventh day, when the patient went to the Ida Convalescent Hospital, it was only packed with a small piece of gauze. The button was passed on the twenty-fourth day. When the patient went home on Oct. 30th there was no abdominal tenderness and nothing at all suspicious could be felt. The sinus admitted a probe for three-quarters of an inch, but it evidently extended deeper. Only a small amount of discharge persisted. The appetite was good and the bowels acted regularly. In appearance there was so great an improvement that on returning from a holiday I had passed her bed without recognising her. She must have gained considerably in weight and she expressed herself as feeling better than she had done for many months. Since her discharge she has attended as an out-patient and when last seen, on Feb. 11th, 1898, the sinus had soundly healed almost from the moment of the discharge of two silk ligatures a week before. Her weight has continued to increase slowly since observations were instituted and she is to all appearance perfectly recovered and in good health. Once recently she has had some slight intestinal derangement but it was only temporary and passed away without treatment. There is no reason to suppose that it was other than purely accidental and it is only mentioned now in view of the future possibilities of such a case.

Description of the specimen.—The upper section has been made through the ileum close to the ileo-cæcal valve and the lower section well to the right of the attachment of the great omentum to the transverse colon and consequently in the immediate neighbourhood of the splenic flexure. The bowel removed includes, therefore, the cæcum and vermiform appendix, the whole of the ascending colon, and the whole of the transverse colon as far as it is possible to ascertain. The specimen, after being kept for months in spirit, measures 10½ in. in length and 11 in. in circumference at the thickest part. The mass of the growth extends from 2½ in. to 3 in. from the extremity of the cæcum to within 2 in. from the end of the specimen, and its length is about 5½ in. Attached to the specimen is what appears to be the whole of the free part of the large omentum. It is adherent over the anterior surface of the intestine, and above the latter can be seen the line of section made just before the omentum passed to the stomach. The broad cut surface of the meso-colon can be recognised behind this. The specimen has been slit open on its posterior surface and the growth is seen to completely encircle the lumen. It infiltrates the walls of the gut but not its serous covering, and it has not produced any marked external puckering, though from the cross section of the growth it is evident that a good deal of contraction has taken place. The attached base varies in extent at different parts of the circumference from 2 in. to 3 in. in the longitudinal direction of the bowel. It is thickest posteriorly where its cross section measures from 1½ in. to 2 in. in different places. The

lumen of the bowel is completely filled by a large cauliflower-like mass which has sprouted both above and below the main growth. Its lower end extends for a couple of inches below the attached portion and tapers to a point. Fæces can only have filtered through the interstices of this

FIG. 2.

The specimen has been opened along its posterior surface. The cross section of the ileum can be seen at the right hand upper corner. The figure is about one fifth of the actual size of the specimen.

mass. The vermiform appendix was unfortunately cut across in removing the growth and has not been preserved. It was dilated as if from back pressure.

A microscopical examination of the tumour was made for me by Mr. Stott, the honorary pathologist to the infirmary, who reported that it was a columnar-celled epithelioma: "Throughout the section there were irregularly shaped spaces filled with columnar cells. In some of the spaces there was a gland lumen, in others the cells completely filled the spaces."

The position occupied by the tumour in this case was a very unusual one for a mass in the transverse colon. There can be no question that it reached that position in consequence of its weight. The late appearance of the tumour in the loin and its marked lateral mobility to the left are both consistent with this fact, and certain features of some interest that were observed during the progress of the case were associated with this altered position of the large gut. It is probable that the growth began in the transverse colon near to the hepatic flexure, which gradually became straightened out as the ascending colon was involved by its lateral extension. The contracting nature of the growth not only diminished the length of the affected segment, but gave it a much greater rigidity, and by crowding together the ascending and transverse mesocolons produced the greatly thickened pedicle which constituted one of the chief anxieties of the operation. A change in the normal relations of the various parts resulted from the gravitation of the bulky tumour, the rigid intestine rotating upon an antero-posterior axis so that the heavy end came to occupy the loin, whilst the cæcum was tilted above it and lay in contact with the under surface of the liver. Consequently upon this change in position of the transverse colon the stomach was pulled downwards and to the right until it lay beneath the umbilicus, and this altered position of the stomach, in its turn, would lead to kinking of the duodenum at the junction of its first and second parts, where the moveable portion joins the fixed. Most probably the obstruction which called forth the vigorous muscular contractions of the stomach so noticeable after the removal of the tumour arose in this way.

An attempt may be made to explain the hiccough which was so marked a feature on the first few days following operation upon anatomical grounds. It was probably occasioned by the ligatures which were applied to the great omentum along the great curvature of the stomach. These must have included many offsets from the sympathetic nerves on the right gastro-epiploic artery which originate in the solar plexus surrounding the cœliac axis. From this also the diaphragmatic sympathetic plexuses arise, and the one which accompanies the right diaphragmatic artery communicates with the phrenic nerve on the under surface of the diaphragm.[2]

There are two practical points connected with the operation which merit some attention. I prefer to use Mayo Robson's bobbin wherever possible because I believe it gives greater security, and I hold Murphy's button in reserve for those cases where the condition of the patient makes it imperative to cut down the time spent on the operation to the smallest possible limit. It was for this reason that a Murphy's button was used in this case, but the tension upon the two ends and the depth of the upper one were such that I am convinced that an attempt to use the bobbin would have failed to secure a satisfactory union. The experience therefore gained from this case inclines me to the belief that in exceptional instances a Murphy's button may be found of use where union by suture upon one of the various forms of bone bobbin is impracticable. The other point is the plan that was adopted of packing down to the seat of union with gauze. In the last volume of the Transactions of the Clinical Society (vol. xxx., p. 89) Mr. Sheild describes a case of excision of the cæcum in which on account of similar doubts as to the vitality of the ends of the bowel the same method was used. The value of the proceeding was in both cases unmistakeable, and in my case by preventing a general extravasation of fæces or a localised fæcal abscess it undoubtedly saved the patient's life. Had I packed in another case of removal of a growth from the sigmoid flexure where the meso-sigmoid was so contracted that the proceedings could not be carried on outside the abdomen the patient would have been spared the long anxiety of a deep-seated pelvic abscess and its subsequent surgical treatment.

In those cases of resection of the bowel in which gauze-packing down to, and around, the union is employed any leakage taking place from imperfect suturing or from sloughing edges does so into a cavity communicating freely with the exterior and walled off from the general peritoneum by the adhesions induced around the packing. The deep granulating cavity which results rapidly dwindles to a sinus, and as its deeper parts cicatrize the closure of the fæcal fistula may be counted upon with considerable confidence. Gauze-packing will, I believe, prove to be of great value in preventing the serious and often fatal complications resulting from leakage after resection of the intestine, and as such complications constitute the chief danger after these operations a method which can do so much to avert them is worth a more extended application in suitable—i.e., in doubtful—cases.

In conclusion, I would gratefully acknowledge my indebtedness to the resident in charge, Dr. J. A. Clough, who by his skilful assistance at the operation and his subsequent attention to the patient contributed not a little to the successful issue of the case, whilst by his notes he has enabled me to record it.

Leeds.

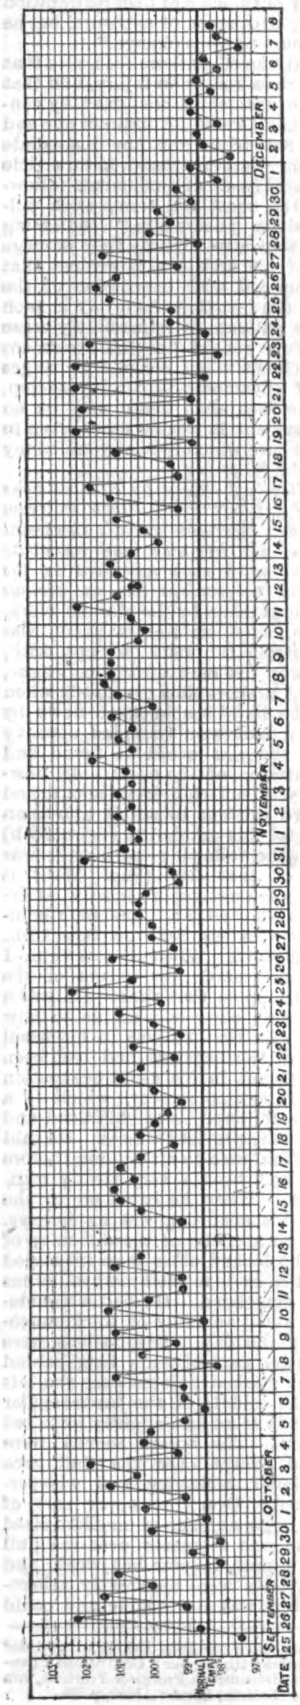
THE YARROW HOME FOR CONVALESCENT CHILDREN, BROADSTAIRS.—This home, which has been established with the object of providing accommodation for children of the better classes, has issued a satisfactory report and balance-sheet for the year ending December, 1897, but it is pointed out that while the number of admissions during the summer months is satisfactory the applicants are fewer between October and April than during the rest of the year. The trustees wish it to be generally known that the institution is specially designed for a winter residence. "It is warmed and ventilated and its grounds have sheltered walks and shrubberies and it is in all respects as serviceable and advantageous for weak and ailing children in the winter as it is during the summer months." The income from investments amounted to £3024 5*s.* and the payments from the parents or friends of the children to £645 5*s.*, making the total sum received during the year £3669 10*s.* The total ordinary expenditure under all heads amounted to £2728 19*s.* 6*d.*

ON

PNEUMONIA FOLLOWING INJURIES TO THE CHEST AND THE POSSIBLE OCCURRENCE OF PULMONARY TUBERCULOSIS AS A SEQUENCE TO TRAUMA.



BY THOMAS HARRIS, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY AND LECTURER ON DISEASES OF THE RESPIRATORY ORGANS IN OWENS COLLEGE.

THE most diverse views have been held and the most contrary statements made in reference to the relation of injuries of the chest to acute pneumonia, and these diverse opinions are, I believe, held by many at the present time as well as being evident in the writings of older authors. It is proposed in the present communication to consider first whether pneumonia does or does not follow as a consequence and is not a mere coincidence to direct injuries to the chest, and also whether in rare cases we may not have pulmonary tuberculosis supervene upon, and be directly traceable to, such injuries. It seems advisable to leave out of count penetrating wounds of the thorax and the action of various bodies gaining entrance to the lungs by the respiratory passages. Grisolle,[1] who was such a careful observer and wrote so cautiously, says that pneumonia sometimes follows the attempt to lift a heavy burden, that he has observed several such cases, and quotes Frank as having made a similar observation, but, he adds, nothing is rarer than to see pneumonia following contusions of the thorax whether there has or has not been fracture of the ribs. Hæmorrhage often may take place into the lung in such cases but rarely does pneumonia follow, and he summarises the question by saying that the pulmonary tissue has less tendency to inflame under the action of external violence than one would *a priori* suppose to be the case and that pneumonia developed by traumatic causes remains, in the majority of cases, circumscribed. Wunderlich,[2] on the contrary, says that he has often seen pneumonia beginning after severe contusions of the chest and running a typical course and he regards that cause as not an uncommon one. Jürgensen,[3] on the other hand, is just as positive in upholding the other view. He says no injury to the chest can produce a true croupous pneumonia and he somewhat sarcastically criticises the frequently quoted case of traumatic pneumonia related by Morgagni [4] by saying that it illustrates the lack of critical judgment with which observations are sometimes made. Coming to more recent times we find that, while Fagge [5] says that true pneumonia is not set up by local injuries to the chest, wounds to the lungs, or foreign bodies in the bronchi, Osler [6] briefly affirms that pneumonia follows traumatism with great frequency, more particularly injury to the chest. Sturges and Coupland[7] in a very able and cautious criticism of the relation of pneumonia to trauma summarise the question as follows: "Lobar pneumonia does undoubtedly sometimes follow injury, either immediately or within a short interval. In some instances this sequence is accidental, the inflammation not being caused by the injury but only brought to light through its agency. In others there is a real but indirect relationship; the pneumonia arises, that is to say, not from any harm done immediately to the lung, but from the nervous shock which bodily injury, whether of the chest or elsewhere, is apt to produce, and which, in common with fatigue, destitution, and alcoholic excess, predisposes the individual to such attacks. We have here, in fact, only a further illustration of the occurrence of true lobar pneumonia of definite duration and orderly course, not as a consequence of exposure, but as a real expression of some obscure nervous change."

It is evident that these last-named authors recognise that in some instances pneumonia does follow an injury, and that the sequence is not always an accidental one, but they consider that the relationship of the two is an indirect one and that the inflammation does not arise from any immediate injury to the lung. Litten,[8] on the other hand, in an article published in 1882 records several cases of pneumonia following directly on an injury to the chest and terms such pulmonary affections "contusions pneumonia," indicating clearly that he believes that they arise directly from damage to the lung. From perusal of his article it is evident that he considers the cases as associated with concussion of the lung. He calls attention to the fact that the injury in such cases often did not cause the patients to immediately cease work and that they often only sought hospital treatment some little time after the accident when secondary changes in the lungs in the shape of pneumonia began to develop. He also lays stress upon the fact that there may be no external signs of contusion evident in severe cases, even in some which end fatally. The case which specially called my attention to the subject was the following.

Injury to the chest, immediately followed by clinical signs of acute lobar pneumonia of the left side; death in from ten to eleven weeks afterwards; necropsy reveals thickened pleura over the lower lobe of the left side and an acute tuberculosis of both lungs, but much more advanced in the left lower lobe; old obsolescent tuberculous foci in various parts of the lungs. (From notes taken by the clinical clerk, Mr. E. W. Floyd).—A man, aged sixty-eight years, was brought to the Manchester Royal Infirmary on Sept. 25th, 1897, and was admitted under the care of my colleague, Mr. Southam. He stated that a short time previously when about to get into a tramcar he had been knocked down by the pole of a waggonette and had been trampled upon by the horses. No fracture of the ribs could be found and there was no evidence of contusion of the chest. As, however, he appeared to be ill, was suffering from shock, and was an old man, it was deemed prudent to admit him as an in-patient. On the evening of his admission (Sept. 25th) the temperature was 97 6° F., the following morning it was 98·4° and in the evening of that day (Sept. 26th) it rose to 102 2°. Evidence of pneumonia shortly afterwards appeared and as this showed no signs of resolution he was transferred to one of my beds on Oct. 13th, eighteen days after the accident. When I saw him I questioned him particularly as regards the nature of the accident and as to his health up to that time. He was a very intelligent man, gave a very clear account as to how the accident happened, and said that he was in his usual good health up to the time of the accident and had been engaged on the day of the accident in his usual occupation of an hydraulic packer. This employment, which is a laborious one, he had always followed since childhood and he had apparently never had any previous illness. He said that he had never had a medical man to attend him before during his whole life. He had been a very steady man, though not a total abstainer. When he came on to the medical side of the hospital his condition was as follows. He was propped up in bed on account of the difficulty of breathing. He was a man who looked older than his stated age (sixty-eight years). He had a well-marked arcus senilis; he was considerably emaciated. He had a troublesome cough and brought up about an ounce of thick mucopurulent expectoration during the day. Respirations were 30 per minute. Over the upper part of each lung behind there was good resonance, but marked dulness over the left base, extending as high as the middle of the interscapular region. There was no dulness in front but slightly impaired resonance over the left apex. The breath sounds were normal in front and behind except over the dull area at the left base, where tubular breathing and whispering pectoriloquy were marked. Over the upper part of the dull area there were a large number of medium-sized bubbles. The vocal fremitus was increased over the dull area. The pulse was 120 per minute, regular but weak, and easily compressible. The arteries were apparently atheromatous. The cardiac apex beat was not visible and could

not be felt. There was no increase of the cardiac dulness and the heart-sounds were weak but unaccompanied by any murmurs. The tongue was covered by a thick white fur and the bowels were somewhat constipated. The urine was of specific gravity 1020, acid, contained neither albumin nor sugar, but deposited urates on standing. The sputum was examined for tubercle bacilli with negative results. The patient remained much in the same condition as regards the pulmonary physical signs, but gradually got weaker. On Nov. 20th there was a note that the sputum was again examined for tubercle bacilli, but with negative results. He gradually became weaker, no improvement took place in the condition of the lung, the urine from being free from albumin showed a trace of that substance on several occasions, and he died on Dec. 8th, between ten and eleven weeks after the accident, apparently from simple exhaustion.

During the last two weeks of his illness he was too ill for any careful examination to be made as regards the condition of the chest. The record of temperature is shown on the accompanying chart. It will be noted that in the evening of the day following the accident a rise of temperature to 102·2° was recorded and that during the next five weeks it was an irregular type of temperature, varying usually between 99° and 100° and occasionally reaching 102°. The type of temperature is not the one most usually seen in acute pneumonia, but such an irregular temperature is probably far from being an uncommon type when pneumonia attacks people advanced in years. After the first five weeks for about a fortnight the temperature became of a more continuous type, being generally between 100° and 101°; then this period was followed for about a week by a distinctly intermittent temperature, the evening record being 102°, whilst in the morning it was normal. During the last week of life there was absolutely no rise of temperature whatsoever, which is a remarkable fact in view of what was found at the post-mortem examination.

The necropsy was made on Dec. 9th, 1897, by Dr. Kelynack, the pathological registrar of the infirmary, and the following is an abstract from the report. The body was extremely anæmic and there was marked general wasting. The skin was harsh and wrinkled. There was no sign of fracture of the ribs or injury to the pleura. The left pleura presented extensive pleurisy of old date, especially over the lower lobe of the lung. There were old pleuritic adhesions both over the base of the lung and at the left apex, over the former part being much more general and extensive than over the latter. The right pleura presented indications of acute fibrinous pleurisy, evidently of tuberculous origin, as miliary tubercles could be seen at various parts of the pleura. The weight of the right lung was 1 lb. 11 oz. and that of the left 1 lb. 12 oz. The left lung (see illustration) was almost entirely consolidated throughout its lower lobe by disseminated caseous tuberculous pneumonia. Many of the patches were softening and forming small cavities. At the upper part of the left lower lobe the consolidation appeared somewhat firm as though of old standing. The whole of the upper lobe presented patchy pneumonic consolidation, some of which was certainly tuberculous; but as regards some of the other foci no definite statement could be made as to whether they were simple inflammatory or tuberculous lesions. The consolidated areas in the upper lobe had a greyish white granular appearance, but there was no evident softening or formation of cavities throughout the upper lobe with the exception that in the extreme apex there was a small cavity evidently of very old standing. The apex of the left lung was firmly adherent to the chest wall and on separating the adhesions the above-mentioned old tuberculous cavity was opened into about 1 in. by ½ in. in diameter. The walls of this cavity were extremely thickened and pigmented. At the lower part of this cavity in the substance of the lung was a caseo-calcareous deposit encircled by firm, hard, dense pigmented tissue. The pleura over the lower lobe, as previously stated, was much thickened and of a firm fibrous nature, and between the upper and lower lobes there was firm adhesion (see illustration). With regard to the right lung, there was slight thickening of the pleura over the apex, which apex presented an old caseous and fibrous focus. There were numerous areas of acute tuberculous consolidation throughout this lung, less marked at the base than in the upper lobe, but all were of recent development and less advanced than in the lower lobe of the left organ. The pleura over the lung was studded with miliary tubercles and similar lesions could be seen throughout the lung. The bronchial glands were deeply pigmented and apparently tuberculous. The impression conveyed from an examination of the lungs was that there had been old healed phthisis in the upper lobe of both lungs, which had perfectly healed, and which showed no signs of activity; that recently an acute tuberculosis had developed throughout both lungs, and that this acute tuberculosis presented no relation whatsoever to the old patches of healed phthisis; it did not appear, so far as could be determined from the pathological appearances, that absorption of the tuberculous virus had taken place from the old foci, or that those old foci had been the cause of the recent eruption of tubercle. The thickened pleura over the lower part of the lung was probably the remains of the attack of acute simple pleuro-pneumonia with which his illness had commenced immediately after the accident. Portions of the lung taken from the lower part of the upper lobe and from the lower lobe were examined microscopically and were found to present the usual typical tuberculous features. The giant cells were very marked and numerous. All the other organs were examined, but no tubercles were found in other parts and there was no other disease found than that mentioned with the exception that the vessels of the brain were slightly atheromatous and the kidneys, the united weight of which was 6 oz., were slightly granular and of increased consistency, and the cortex of these organs was slightly diminished.

Considering the history of the case together with the pathological appearances, the inference appears to be justified that we had to do with a pneumonia of the left lower lobe consequent upon an injury to the chest and that the pneumonia had a few weeks before death become infected by the virus of tubercle and an acute tuberculosis had resulted, which acute tuberculosis was most marked and most advanced in the lower lobe of the left side and had probably originated there. As to the source whence the tuberculous

Section through the left lung showing the thickened pleura over the lower lobe and the tuberculous or caseous pneumonia more advanced in the lower than the upper lobe.

virus was derived there may be a difference of opinion. From the fact that there were several patches of healed tubercle it is evident that we had to deal with a subject who was predisposed to tuberculous disease and it is possible that the virus had been absorbed from the old tuberculous foci and had been the cause of the acute eruption of tuberculosis which was the immediate cause of death.

It is now a generally accepted fact that old obsolescent tubercle is of very frequent occurrence in the lungs. Some years ago I published details [9] which showed that no less than 38·84 per cent. of all the bodies examined in the post-mortem department of the Manchester Infirmary of persons dying from various diseases and accidents over the age of twenty years presented such signs of obsolescent tubercle. Such figures are remarkable, but they quite accord with the observations of other authors. It appears, however, equally probable that the original acute pneumonia had so lowered the vitality of the individual and the lungs that tubercle bacilli, which had entered in the inspired air and which we now know are so widely disseminated in the air and in various places, had found in the old inflamed and unresolved pneumonia of the lower lobe a favourable nidus and that they had there started the acute tuberculosis.

The only published case that I have been able to meet with at all closely resembling the one here recorded and bearing upon the question of the traumatic origin of pulmonary tubercular phthisis is one which was published on Nov. 15th of last year by Dr. O. Schrader,[10] but in that case the result was the more fortunate in that at the time the case was published the patient had apparently recovered. The case was that of a man, twenty-nine years of age, who had enjoyed extremely good health and came of a very healthy stock, no history of tuberculosis existing in the family. The patient received an injury of such a serious nature that he remained unconscious for a quarter of an hour afterwards. On the evening of the same day he began to feel ill and although he attempted to work on the following day he had to cease work in consequence of feeling unwell with headache and feverishness and on the next day he was admitted to the hospital. On admission an excoriation was evident over the right shoulder blade and there were a few physical signs over the lower part of the chest on that side. The diagnosis of pneumonia of the lower and middle lobes of the right side was made. Later the temperature became of a more intermittent character and the physical signs extended over the whole of the left lung. The sputum about six weeks after the accident showed the presence of tubercle bacilli. Later the general condition improved, weight was gained, the patient lost his cough, became free from fever, and no tubercle bacilli could be found in any expectoration. At the date of the communication there were no signs to be found of any disease in the lung. Dr. Schrader considered the case one of tuberculosis resulting from an injury, the tuberculosis having been probably preceded by a simple pneumonia, but, as he says, up to that time there could not be found published any proof that a trauma in a healthy individual could produce pulmonary tuberculosis. It has long been a recognised fact that acute disseminated miliary tuberculosis may follow immediately upon injuries of, and surgical operations upon, various parts. Quite recently Dr. F. Parkes Weber [11] drew attention to the possible medico-legal interest in certain such cases.

As to whether or not my case is a mere coincidence or is an instance of true traumatic or contusion pneumonia, followed by the development of pulmonary tuberculosis one cannot be dogmatic, but from the distribution of tuberculosis in the lung, true basal tuberculosis being so rare, one is inclined to regard the case as a direct consequence of the injury and not to regard the association of the pulmonary lesion and the trauma as a mere accidental one. It appears quite probable that the accident occasioned the pneumonia and that this predisposed the lung to tuberculous disease. As to whether the tuberculous virus was derived from the old obsolescent tuberculous foci or whether it gained access to the lungs from without appears to be a matter of minor importance. The case would appear to illustrate the fact to which attention has been called by Delépine [12] and others, that we must consider the condition of the individual and of the lung in reference to the development of tuberculosis in the lungs—that we have to regard the pre-tuberculous state of the organ in reference to the pathogenesis of pulmonary phthisis. Many causes may be predisposing or exciting ones for the development of tuberculosis in the lungs and one of the most uncommon, but yet from the pathologist's and the medical jurist's point of view not an unimportant one, may be direct injury to the chest.

VITALITY:
AN APPEAL, AN APOLOGY, AND A CHALLENGE ADDRESSED TO BROTHER PRACTITIONERS.

BY
LIONEL S. BEALE.

BEFORE considering the part played by vitality in various departures from the healthy state in some of the most important tissues and organs I am anxious that the attention of the members of the profession should be accorded to a short summary of the most important of the conclusions arrived at and stated in the several papers on Vitality already published in THE LANCET during the past two years.

It seems to me that the time has arrived when this most important question should be carefully considered by every one of us with reference to its bearing upon medical and surgical practice as well as on account of its surpassing general interest. We do all we can to keep our fellow creatures at every period of life in mental and bodily health and have to advise them how to live so that they may efficiently and happily discharge their several duties with as little wear and tear and damage to their tissues and organs as possible. It is our duty, therefore, to ascertain and explain how natural vigour and healthy action may be prolonged into old age and in what manner degenerative changes and impaired action of most important organs may be prevented or retarded in each case, and the necessary end as far as possible postponed. In all these natural changes vital action, Vitality, is of the first importance. Indeed, all questions connected with the nature and actions of all things living must always be to us of the greatest interest in consequence of their bearing upon the training and general management of children, upon public health, upon the working capacity at all ages, and particularly upon the numerous departures from the healthy condition which engage our practical consideration in the several departments of Hygiene, Medicine, and Surgery. I propose, then, to ask my readers to consider with me some of the general changes in living matter and its altered relations when its action is but slightly deranged and it begins to pass from the normal health condition towards that of more or less serious derangement and actual disease—an inquiry of the greatest interest. Most striking, too, are those very slight departures from the normal state at different periods—infancy, childhood, adolescence, maturity, and old age—whether regarded from the purely scientific or from the practical point of view.

I appeal to every member of the medical profession in all parts of the world because each has, in fact, had a scientific training not only in one but in several departments of scientific knowledge. The general structure of the higher organisms and of man as well as of the simpler living things and plants, the minute structure of the several tissues and organs, the physical and chemical phenomena of living things, the phenomena which distinguish the living state from every other state in which matter is known to exist, the minute changes occurring in various departures from health, and the exact points in which diseased tissues and organs differ from those which are healthy are of the greatest

interest. Without such knowledge, which is continually advancing, we should not understand pathological changes and should not be in a position to be of the greatest service to our patients.

Many medical men have been skilful scientific observers, and indeed some have attained equal eminence in science and practice, and recently our profession has been honoured by one of its most distinguished members, like more than one predecessor, being elected President of the Royal Society and of the British Association for the Advancement of Science, but Lord Lister is the very first practitioner upon whom a peerage has been conferred.

Many thoughtful men, led away by the plausible statements so frequently repeated during the last thirty years, have accepted the purely physical and chemical doctrines concerning life and all living nature, notwithstanding the conviction, at least in some cases, that these views were incompatible with many facts of general interest and observation, and not in accordance with the phenomena they themselves have observed in others or with certain changes which they knew were proceeding in their own organisms. Fully conscious of the complexity of the whole question they scarcely dared to express an opinion, and thus involuntarily were included among the supporters of views to which, though popular and fashionable, they were entirely opposed. But at last the chemical and mechanical doctrines of life seem to be really giving place to more rational views based not upon so-called "working hypotheses" and "tendencies of thought," but upon facts of observation and things to be seen and studied by all who can use the microscope, and which are in accordance with our general knowledge derived from long association with and investigation of the highest living forms in nature living under various conditions.

It is now more than forty years since the results of many observations with high magnifying powers and experiments led me to conclude that every living thing and everything that had lived in time past was absolutely dependent for existence upon the operation of *vitality*—a power manifested by living matter only, and restricted to organisms in or upon the earth or water or in the lower strata of the air.

In many communications I showed that although the real living matter was most inconspicuous and was often unrecognised altogether, it was by far the most important of the various anatomical constituents of all tissues and organs of living things at every period of life. I referred to its powers of growth, multiplication, and action, and drew attention to the important points in which this living matter absolutely differed from matter in every other known state or condition; and I claimed that in all cases vital action was due to these powers distinct from all ordinary forces and properties of ordinary matter, and capable of overcoming these and preventing, for the time being, their operation.

So far from the existence of vitality having been disproved, the more minutely investigation has been carried the stronger has become the evidence in its favour. Probably very few scientific men would now dispute or deny its operation upon the matter with which it is temporarily associated. All who rely upon evidence must feel satisfied that the more recent discoveries as to the constitution of our sun and the planets as well as the fixed stars, render it most improbable that life exists in these or other orbs. By increased knowledge the reason has become convinced that vitality, as we know it, is thus limited, and in its nature far removed from any of the tremendous physical phenomena which have been in operation during millions of years millions of miles away from us.

The exact nature of the purely vital phenomena and the various circumstances under which they are modified in nature and particularly in our own fellow creatures in various departures from the normal condition are questions which are constantly presenting themselves to our minds for consideration, although our longing to know more cannot as yet be satisfied. But, on the other hand, it is impossible to accept the assurance that all the phenomena of living things, so very different from any characteristics of the non-living, are due to physical and chemical actions only. The movements of clear structureless living matter have for many years been ascribed to chemical change, but no one among the advocates of this doctrine has attempted to explain how, when, or why the chemical change begins or by what means the special chemical changes characteristic of different kinds of living matter have been established. The view that vital action somehow originates in, or is a modified form of, any of the ordinary forces or properties of non living matter is contradicted by the fact that these are *actually overcome and are in abeyance in matter which exhibits vital action as long as the living state of the matter continues.*

The evidence is now so conclusive that I venture to think that most thoughtful practitioners are already convinced that we, and all for whom we are responsible in sickness, are far removed from the category of machines with mechanical contrivances which men design and make, the action of which they superintend and regulate, and the damaged or worn part of which can be repaired or replaced. All living things grow from the structureless, and not only are all their tissues formed from the structureless, but it is very doubtful whether there is an action which is not directly or indirectly dependent upon the vital changes in structureless living matter. We are not machines; we are not governed by, or the results of, chemical and mechanical changes. Our life is not the mere outcome of chemical and mechanical forces. The facts of observation and the results of experiment not only at this time prove that it is not in accordance with reason to assert that man is a machine and all his actions are mechanical, but that no one acquainted with the well-known facts and guided by reason could have assented to this proposition at any time during the past fifty years. Man is a being whose living matter is endowed in a special manner with powers peculiar to man alone, his living matter, as we know, being influenced by many chemical substances in a manner different from that in which the living matter of other creatures is influenced by the same substances. The differences in action are not to be accounted for by any physical or chemical properties of the substances which can be obtained from the living matter or bioplasm of man's organism, and those who tell us that such and such things are taken from organisms that were *alive* must bear in mind the fact that the matter they examine and analyse is but the matter that *was* living, and that the things they obtain are but those that result at the moment of or soon after death. To chemically analyse living matter is at present impossible.

We who are engaged in studying the living and in trying to promote and maintain healthy vital changes in every part and organ of the living body, cannot possibly accept the assertions, however often repeated, with regard to the properties and composition of lifeless matter as evidence of the nature of the changes which take place in the matter in its living state. Neither must we allow ourselves to be influenced by arguments based upon the composition and characters of portions of tissues and parts of organisms which are not in a living state, even while the actual living matter, which is less conspicuous but most important, exists.

No wonder that during ages past practitioners who held a high scientific position should have been much interested in anything that seemed likely to throw any light upon that greatest of all scientific problems—the nature, and origin, and destination of life—and particularly of those wonderful phenomena which have been watched with intense interest from the first moment of infant life onwards through childhood, maturity, old age, to death. For who can study even the ordinary actions of the limbs as they slowly become perfected without feeling convinced that such actions are indeed widely separated from any mechanical or other movements in non-living matter—that, indeed, there is no analogy whatever between any parts of living beings and any machines, apparatus or laboratories?

And now let me ask if there is one among us who, having thought over this question of the nature of life, is satisfied with the strange doctrines enunciated in many text-books at this time and the evidence advanced in their support?—anyone who receives the arbitrary dicta authoritatively proclaimed as the teachings of science and reason that we and all our actions, thoughts, hopes, and fears are the results of physical and chemical actions in the material particles of which our bodies are composed?

The physicist and chemist, living amongst and constantly improving instruments and methods of examination, and taking part in investigations of wonderful delicacy and ever approaching nearer and nearer to what they look for as perfection and positive knowledge, naturally look forward to the discovery in living things of some mechanical and chemical microcosm capable of disintegrating, arranging and re-arranging—of analytical and synthetical operations akin to those pursued in their laboratories where with marvellous skill substances that have been united for millions and millions of years are separated from one another and made to yield up matters of wonderful properties which have been

unknown and unsuspected until now. Physicists and chemists look forward with confidence to the synthesis in the laboratory of elements which according to authority combined in nature for the first time, only a few millions of years ago and thus think to acquire a knowledge of the manner in which the first particle of living matter originated and began to live and move and grow and form, to multiply, mature, grow old (?) and die. But in not one of the millions of millions of the successors of that primitive living particle has anything like a laboratory been discovered. However, according to prophecy and the so-called tendency of thought, the naturalist of the future is to discover much that the existing naturalist of to-day fails to discern. But, alas, up to the present moment, notwithstanding our increased and ever-increasing knowledge, living nature still retains many secrets, and no physicist or chemist has yet succeeded in discovering the physical and chemical principles by which even the apparently simple vital movements, to say nothing of the evolution of heat, light, and electricity, by particles of clear, colourless, structureless, living matter are to be explained. So far no substance has been discovered or produced in the laboratory, that lives or moves and grows and multiplies and dies like every particle of matter that lives or that has lived in nature.

As regards the great questions bearing on the nature of life which have been considered by some of the greatest intellects in every generation during the past 2000 years, the latest appeals have been and must continue to be made to ever-progressing science, and it is certain that with the ever-accumulating results of investigation, of new facts, and demonstrations, reason will at last be satisfied. But during recent years thought has been overwhelmed and almost stifled by what purports to be scientific authority—authority based only on confident assertions, arbitrary dogmas and strange conjectures often advanced by highly confident people who seem to have been more successful in gaining the acclaims of the public than the confidence of the thoughtful. And for a long time past not a few reasons, facts, and arguments tending to establish conclusions of a very different kind have been ignored and not unfrequently their advocates intimidated and silenced by self-proclaimed authority.

The following are some of the doctrines still maintained and taught, although they as well as the conclusions involved in their acceptance have been shown over and over again to be opposed to scientific facts and observations and to be contrary to reason. It is improbable that any one of them will ever be established or will in future receive the support of those who have studied the structure and vital phenomena of any organism in the living state.

The living and the non-living are one.

All movements in living things are physical and are due to chemical change.

Life is made up of physical and chemical action.

Vital mechanics—vital chemistry.

Man is a machine and all his actions are mechanical.

The sun is the source of life.

Suns resolve themselves into living things.

Living things are built by the sun.

The sun forms hearts and brains and tissues and organs.

The living comes direct from the non-living.

Plants are nearer to the non-living than animals.

All life came from matter, is due to the ordinary properties of matter, and obeys mechanical laws.

Living "protoplasm" is a proteid and obeys ordinary chemical laws.

The "growth" of living and lifeless takes place in the same way.

Aggregation is a form of "growth."

Crystals *grow*.

(To be concluded.)

ROYAL MICROSCOPICAL SOCIETY.—The next meeting of this society will be held on Wednesday, April 20th, at 8 P.M. precisely, when Mr. Henry Morland, F.C.S., will read a paper on Some Organic Substances of High Refractivity Available for Mounting Specimens for Examination under the Microscope, and Mr. E. B. Stringer one on Instantaneous Photomicrography. At 7.30 there will be an exhibition of Diatoms by Mr. Morland.

NOTES ON A CASE OF PORRO-TAIT'S OPERATION.

BY ALBERT E. MORISON, M.B., F.R.C.S. EDIN.,
HONORARY SURGEON TO THE HARTLEPOOLS HOSPITAL.

ON March 20th, 1897, I was asked by Mr. Moffat Young of West Hartlepool to see the case which I am about to record. The patient was a little spare woman, 4 ft. 2 in. in height, but with no apparent deformity of any of her bones. She was twenty-four years of age. There was a history of rickets in childhood. She was three years old before she could walk. At the age of fourteen years (ten years ago) she came under my care suffering from disease of the left hip-joint and she was confined to bed for six months. This, however, had left no deformity of her limb. Mr. Moffat Young first saw her at 4 P.M. on March 20th. Labour began at 9 A.M., but the pains were not severe. The "waters broke" at 3 P.M. As the presenting head made no progress Mr. Moffat Young examined her carefully and found that the lateral diameters of the pelvis were very much diminished. He concluded that some operative interference was necessary and he asked me to see the patient with him and we met at 9 P.M. The patient had been in labour twelve hours and was getting exhausted. The uterus was firmly contracted, but the pains were feeble. On making a vaginal examination the sacro-sub-pubic conjugate was found to be apparently normal, but the lateral diameter of the pelvis was much contracted, only admitting two fingers. The head could be felt high above the pelvic brim. I agreed with Mr. Moffat Young's opinion that there was no chance of delivering the child per vias naturales and the following operation was performed. The patient was chloroformed in bed and when under the anæsthetic she was lifted on to the table. Her abdomen was cleansed with soft soap, turpentine, and ether and purified with 1 in 500 corrosive sublimate lotion. An incision was made in the middle line from the umbilicus to about 1 in. above the pubes and the peritoneal cavity was opened. This wound being too small to allow of the uterus being lifted out of the abdomen was enlarged upwards with scissors. The uterus was then tilted out of the abdomen and a large sponge was packed behind it over the intestines, which were consequently not exposed during the operation. A piece of drainage-tube was passed round the uterus low down and tightened to form an elastic ligature, care being taken to avoid the bladder. The uterus was then opened close to the fundus by a longitudinal incision in the middle line, the fœtus extracted, the cord clamped with two pairs of forceps and divided, and the child handed to a nurse. The uterus was next cut away above the elastic ligature, traction being exerted on the tubing whilst this was being done. The ligature was finally tied in a double knot and a Tait's pedicle pin was passed through the stump. The exposed mucous membrane of the cervix was swabbed with pure carbolic acid and dusted with iodoform and boracic acid. Douglas's pouch was sponged out and the parietal incision was closed with silk sutures, the stump of the uterus being fixed in the lower angle. The wound was dressed with cyanide gauze and wood-wool. The patient was put back to bed in twenty-five minutes. She did not lose more than half an ounce of blood and looked well.

The subsequent history of the case was as follows. Vomiting was troublesome for twenty-four hours. The patient's temperature attained its highest point—99° F.—on the first evening after the operation. The stitches were removed on the eighth day. The pedicle sloughed off on the tenth day and the patient was allowed to get up on the twenty-first day. The child was healthy when born and is now alive and well. The mother did not suckle the child.

Although the operation was performed under disadvantageous surroundings and circumstances the case pursued an entirely satisfactory course throughout. The patient had to be treated in one room of a small cottage hardly large enough to contain an ordinary operating table. The only light available was that supplied by a small paraffin lamp, and it proved to be so feeble an illuminant that Mr. Moffat Young had to hold the lamp close to the patient's abdomen with one hand whilst he administered the anæsthetic with the other,

so that to his skilful assistance the result is largely due. My reason for choosing Lawson Tait's modification of Porro's operation on a delicate woman in the surroundings mentioned was the ease and rapidity with which it can be performed. To entirely draw out the uterus a larger incision in the abdominal wall is required, but this is more than compensated for by the ease with which the elastic ligature can be applied before the uterus is incised, thus reducing the loss of blood to a minimum and preventing the soiling of the peritoneal cavity.

Hartlepool.

UTERUS UNICORNIS.

BY HEYWOOD SMITH, M.A., M.D. OXON.

CASES of true uterus unicornis are so rare that no apology is needed for relating such a case and drawing attention to some features that seem common to most and pointing out some characteristics that seem to make this case a very rare specimen, if not unique.

The patient, who was thirty-three years of age, had been married for four years, and had one child two and a half years old, was brought to me by her husband on Oct. 6th, 1896. The catamenia began at the age of twelve years. They were regular, lasting from four to five days, but lately they had been accompanied by pain in the back and in the right inguinal region. She had suffered from backache for the past twelve months and this had been more severe since August. The pain was worse at the periods. Micturition had been frequent for six months. The pain in the right groin was now constant. She could not walk well and she was getting worse. On vaginal examination the os uteri was found to be rather patent; the canal was soft and slightly irregular. The uterine sound passed in the natural direction for three and a half inches. Behind the uterus and slightly to the left of the median line was felt on conjoint rectal and vaginal examination a body rather firm (? cystic), immoveable (? adherent), and tender. From the dragging pain on the right side a diagnosis was made of the right ovary prolapsed and the left enlarged, inflamed, and adherent. The patient had consulted me twelve years previously for dysmenorrhœa when there were some anteflexion and stenosis. The canal was dilated and she wore a glass stem and a small Hodge's pessary for some months with great benefit.

I sent her to Mr. Bland Sutton for an opinion and he agreed with me that there was an inflamed ovary, probably adherent, and he advised an operation. I therefore on Oct. 13th operated, Mr. Bland Sutton kindly assisting. On opening the abdomen I found an elongated body and brought it to the surface; it looked like the uterus, but the fundus, instead of being broad and flattened antero-posteriorly, was rounded at the top and on the left side, which was quite smooth down to the bottom of the pelvis. On the right the oviduct and the ovary were traced out and brought to the surface, when the ovary was found to be a little larger than normal with the distal one-third distended with blood and a scar at its extremity blood-stained; there were several small cysts, but nothing abnormal. As she had asked me, if possible, to leave one ovary so as not to preclude the possibility of her having another child, and as she apparently possessed only one, I decided to leave it. There was a thickened and pallish band partly surrounding the uterus at the junction of the cervix and body, slightly irregular. We then proceeded to search for the other ovary but failed to find it. At the bottom of Douglas's pouch there was a flattened irregular patch, but not marked enough to have been that organ. We then examined for the tumour we had felt on the left posterior aspect of the pelvis, and Mr. Sutton, recognising the fact that uterus unicornis is usually associated with abnormality of the kidney on the same side as the absence of the uterine appendages, at length satisfied himself that it was the kidney, of normal size, two-thirds of it lying below the brim of the pelvis; this I also verified. The right kidney was normally situated. The wound was then closed in three stages. The patient made a good recovery and lost her pain.

I would draw attention to the special features in this case, first of all remarking that the developed side was the right; this has been the case in all the recorded cases which I have looked into. An unusual feature was that there were no rudimentary structures on the left side, no broad ligament, no round ligament, no ovary, no oviduct, but only smooth peritoneum. The left kidney existed and was apparently normal in size and consistency, but greatly displaced. No attempt was made to trace the ureter. The uterine cavity was an inch longer than normal, and the patient had had a child. It must be remembered that the specimen was not removed and lying on a plate for careful examination, as most of the former specimens have been, but we were inspecting a living body during the course of an operation and therefore were not justified in making a prolonged examination.

With the aid of J. S. Billing's most valuable catalogue (I could not find the subject in Neale's "Digest") I searched for records of similar cases and have appended a few short abstracts to make this observation more complete, thinking it may be of use for further reference.

Mr. Nunn,[1] of the Middlesex Hospital, showed on Feb. 1st, 1859, a specimen from the dissecting-room from a subject, aged thirty-five years, of uterus unicornis. In this case it was the left side which was undeveloped. But in this case, though the oviduct was undeveloped, yet its fimbriæ were present and the ovary was discovered at the brim of the pelvis. There was also a broad ligament on that side.

Sir W. Turner,[2] Professor of Anatomy in the University of Edinburgh, has written an article on uterus unicornis. The malformation was discovered in the body of a woman, past middle life, in the dissecting-room. The uterus was smaller than normal, its length being 1¼ in. and its breadth 1¼ in. The left side was rounded and on the right only were the broad and round ligaments, the ovary and oviduct. On the left side a band passed which seemed to represent the left uterine cornu atrophied. There was a left ovary attached to the end of this band, small, thin, surfaces flat, with no trace of scars, and there was a short oviduct detached from the left cornu. The cavity of the right cornu measured 2 in. The left kidney was absent, but the left suprarenal capsule was normal. The pelvis was normal.

Dr. Matthews Duncan[3] read a paper before the Edinburgh Obstetrical Society on Jan. 14th, 1874, on a case of uterus unicornis dexter. The subject was sixty years of age and died from cancer of the pylorus. The left kidney, ureter, and renal artery were absent; the vagina and cervix were normal; but there was no passage from the cervical canal to the cavity of the uterus. The uterine body was rather elongated (as in my case) and on the left the organ was free and was covered with peritoneum, there being no trace of the left broad ligament, oviduct, ovary, or left angle of the uterus. The figure[4] accompanying the article is almost an exact representation of the organ in my case.

At the Obstetrical Society Dr. Braxton Hicks showed for Dr. Ogston, jun.,[5] an unilateral uterus and kidney (solitary) with two ureters. The uterus has only its right half developed, its left half, left oviduct, ovary, and broad ligament being wanting. There was no trace of a left kidney, but there was a left suprarenal capsule. The right kidney had two ureters, one being imperforate. The body, pelvis, and external genitals were normally developed.

Dr. Amand Routh[6] also showed at the Obstetrical Society a specimen of a fibroid from a one-horned uterus. This was reported upon by Mr. Alban Doran, Dr. W. S. A. Griffith, and Dr. Amand Routh at the meeting of the society on Feb. 2nd. This is not a true uterus unicornis. Here a tumour has encroached on a district of a normal organ and has dislocated its parts. The left ovary was below the tumour, which was in relation to the broad ligament, and the oviduct was evident. The right side of the uterus was normal.

Besides these cases there are several observations by foreign medical men, but in nearly all of them there existed some rudimentary trace of the appendages of the opposite or undeveloped side and in many there was only one kidney.

[1] Transactions of the Pathological Society of London, vol. x.
[2] Edinburgh Medical Journal, February, 1865.
[3] Obstetrical Journal, vol. i., p. 783.
[4] Ibid., p. 784.
[5] Transactions of the Obstetrical Society, vol. xxi., March, 1879.
[6] Ibid., vol. xxix., Jan. 12th, 1887.

I think that my case is remarkable in that there was no trace either of ligaments or appendages on the affected side, and in the position of the left kidney. As this was partly in the true pelvis and adherent it is a wonder that it was not injured by the passage of the head of the child during labour, but as far as I could ascertain there was no special difficulty or pain at that time. I consider, therefore, that this case is worthy of record, as it seems to be almost if not quite unique.

Harley-street, W.

A CASE OF EXTENSIVE EXTRAVASATIONS OF BLOOD IN VARIOUS PARTS OF THE BODY OCCURRING IN AN ANÆMIC WOMAN.

BY EDWARD JOSEPH BLACKETT, M.R.C.S. ENG., L.R.C.P. LOND.

THE following notes on a case in many respects resembling scurvy may possibly be of some little interest, as no cause could be discovered for the affection and the occurrence of a cerebral hæmorrhage during the progress of the case is, as far as I know, an uncommon complication. Some of the symptoms of scurvy were undoubtedly absent and the case was by no means a typical one; still, taking the case as a whole there might, I think, be found some warrant for designating it by that name. However, I will give the notes and let them speak for themselves, leaving the diagnosis of the case to abler men than myself.

The patient was a woman, aged twenty-eight years, who had had no previous illnesses of a serious nature. Her father is living, but her mother died at the age of forty-eight years from "jaundice" and one brother died from phthisis. I went carefully into the question of hæmophilia, but could elicit no history of that disease; the patient had had several teeth extracted a few months ago, but there was no excessive hæmorrhage after their removal. I saw her in November, 1897, when she was suffering from anæmia and amenorrhœa, the latter having existed since October, 1897. Her usual occupation was that of visiting the sick in some of the poorest districts in London about Soho-square, Golden-square, and Hoxton; but she had not come across any cases of scurvy in her visiting or any infectious diseases except measles, the majority of sick persons she had seen being old people suffering from bronchitis and chronic heart affections; neither had she noticed any very bad smells in the houses—at least, not more so than usual, for the sanitary arrangements of the poor are not of the highest order and bad smells are rather the rule than the exception. She had been visiting in these neighbourhoods for the past six months. The sanitary arrangements of the house in which she lived were excellent and the dietary was good, there being plenty of fresh meat and vegetables. Her appetite as a rule was good, though latterly it had fallen off. She had not been eating any tinned foods. The present illness commenced on Feb. 24th, 1898, when she began to spit blood, her friends thinking it came from her lungs. I saw her on the 28th, when she presented the appearance of a well-nourished young woman. Her cheeks were flushed and her lips were of a dark-purple colour and were swollen—in fact, they resembled large blood blisters. These blisters were broken in places and blood-crust was plentiful; there were patches of purpura on the left side of the chin. The insides of the cheeks were also deep-purple in colour, the left side being darker and more swollen than the right. The gums both of the upper and lower jaws were of the same dark colour but were not markedly swollen; this condition, however, may have been masked to some extent by the quantity of coagulated blood which was present along the margins. The front teeth of the upper jaw were missing and the other teeth were in various stages of decay, though not loose. There was a general oozing of blood from the surfaces of the gums and the mucous membrane of the cheeks. The tongue was coated and was swollen and slightly inflamed. There was no fœtor of the breath. There was rather profuse epistaxis. Nothing abnormal was discovered in the lungs and the heart-sounds were normal. Menstruation had occurred on the 25th and had been rather profuse; this was the first time she had been "unwell" since Oct. 18th, 1897. The pulse was, of fair strength and not rapid, the temperature was normal and the bowels were confined. The source of the hæmoptysis was clearly from the mouth and nose and not from the lungs; the blood, though red in colour, was not frothy. On March 1st there was very little change in the general aspect of the patient, the hæmorrhage still continuing, nearly two pints of blood having been lost (from mouth and nose) since the morning of Feb. 28th. Menstruation was still very profuse. A purpuric rash had appeared on the left leg and thigh. The pulse was slightly weaker and the bowels were open. On March 2nd fresh purpuric spots appeared on the upper part of the chest and around the neck. There were also one or two patches of purpura on the scalp. The lips were less swollen and the inside of the mouth was better. The hæmorrhage was ceasing. On the 3rd the first thing I noticed on seeing the patient was that the left side of the face was paralysed, the right side of the mouth was drawn up, and this was very marked when the patient smiled. The left eye could not be closed as could the right. The tongue when protruded was slightly deflected to the left. The patient had severe right frontal headache. The lips, mouth, and tongue were assuming a more natural appearance. The catamenia had stopped. The temperature was 99·2° F. On the morning of the 4th the catamenia recurred; at first clots were passed, but afterwards liquid blood flowed. The patient vomited and the vomited matter was nearly black, but this was due rather to blood which had been swallowed than to any lesion of the stomach, as she said she often used to swallow the blood which collected in her mouth. The face was still drawn and the headache continued. The purpuric rash was still marked on the left leg and thigh and on the upper part of the chest. There was no hæmorrhage from the mouth or nose. On the 5th Dr. Whipham and my father saw the patient and then came to the conclusion that the case was one closely resembling scurvy in many of its aspects and that the facial paralysis was due to a cerebral hæmorrhage. There was marked reduplication of the second pulmonary sound, but otherwise the heart sounds were normal and nothing abnormal could be detected in the lungs. The catamenial flow was still very profuse and the frontal headache was severe; the tongue was coated, but it was pale; the cheeks were flushed, but the lips and gums had returned nearly to a normal condition. There was slight ulceration on the inside of the left cheek. The pulse was weak, the temperature was normal, and the bowels were open. Nothing worthy of note occurred till the 8th, when the catamenia finally ceased, having lasted almost continuously for eleven days, the usual duration of time being only two or three days. The patient, who had a severe headache, vomited once, the vomited matter consisting of curdled milk and bile, but no blood. On the 10th the tongue appeared to be more deflected to the left and the loss of power in closing the left eye was more marked. The headache had gone. The patient had two attacks of vomiting during the day. The purpuric eruption on the leg, thigh, and body was fading. On the 11th fresh purpuric spots appeared on both elbows and round the waist. On the 14th the patient looked much better; the lips, mouth, and gums were normal, the face was not so much drawn, and the purpuric eruption was fading. On the 18th there was a slight hæmorrhage from the uterus, but it lasted only a few hours. The purpuric eruption had disappeared and the face was nearly normal in appearance.

There has been nothing worthy of note in the further progress of this case; the patient got up for the first time on March 21st, and on the 29th, beyond the fact of feeling very weak, she said she felt quite well. Still the angle of the mouth was slightly drawn up when the patient smiled, but it seemed probable that in time all signs of facial paralysis would disappear and that the patient would make a complete recovery.

The treatment adopted was at first perchloride of iron and dilute sulphuric acid internally and glycerine of tannic acid for local application to the mouth. This was changed on March 3rd to liquid extract of ergot, chlorate of potash, and sulphate of magnesia, and on the 5th a mouth-wash of boro-glyceride and rosewater was substituted for the glycerine of tannic acid. On the 29th the patient was put on solution of strychnia and dilute phosphoric acid. The diet was at first beef-tea and milk with the addition of two fresh lemons daily, and on March 14th solid food was taken for the first time.

Seymour-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A SYMPTOM FOLLOWING ANGINA PECTORIS.

By ALBERT S. WORTON, M.B., C.M. GLASG.

THE following curious sequel of an attack of angina pectoris occurring in a case under my observation may possibly be worth recording. The patient was a woman, fifty-four years of age, who had for many years suffered from cardiac valvular disease consequent on rheumatism, and had within the last three months or so developed symptoms referable to failure of compensation, and with this concurrent attacks of cardiac spasm of the variety known as angina sine dolore. These attacks latterly had occurred daily, each lasting only for a few seconds, but attended always with a marked fear of approaching death. Recently she had drawn my attention to a very curious result of the attack, coming on perhaps twenty minutes or so after the heart condition had ameliorated. This consisted of a feeling of numbness beginning at the extreme tip of the left middle finger, followed immediately by blanching and complete loss of sensation extending gradually up the whole length of the finger until it reached the metacarpo-phalangeal articulation, at which point it was finally arrested without ever proceeding further. By this time the entire finger was, to use her own words, "cold and dead." Unless recourse was had to vigorous rubbing and warming this state would last for about half an hour before sensation spontaneously returned, but five minutes of the above active treatment usually sufficed to restore it to the normal condition. The patient further distinctly averred that it was almost invariably the left middle finger alone which was so affected, although rarely the ring-finger of the same side might also participate, but never under any circumstances whatever were the fingers of the right hand affected. I have never been fortunate enough to actually observe the above sequence of events, but there seems no good reason to doubt statements so definitely put forth and corroborated also by a sister resident in the same house. The phenomenon was obviously due to local vaso-motor spasm analogous to the local syncope of Raynaud's disease and probably its invariable occurrence on the left side is to be accounted for by the much more extensive nervous connexions on this side through the brachial plexus with the cardiac nerve apparatus.

Redditch.

PAROTITIS FROM OBSTRUCTION OF STENSEN'S DUCT.

By R. HILL BROWN, M.B., C.M. EDIN.

THE following case is of interest on account of the rather unusual nature of the exciting cause.

The patient, a married woman, consulted me on account of pain and swelling on the left side of the face. On examination the left parotid gland was found to be considerably enlarged and extremely tender. There was difficulty in opening the mouth owing to the pain and stiffness and feeding was greatly interfered with. On examination of the mouth no unusual features could be detected and the case resembled one of ordinary mumps. There was considerable constitutional disturbance and fever, the temperature being 103° F. The general symptoms became gradually worse. A week after I first saw the patient she complained of a pricking sensation in the cheek as of the presence of a foreign body. On looking into the mouth a small-pointed body was seen projecting from Stensen's duct. It was somewhat firmly impacted in the duct and presented some difficulty to extraction with forceps. The foreign body proved to be a feather about an inch in length, of the kind used in feather mattresses. Almost the whole length of the feather had been embedded in the duct. After its removal a considerable quantity of pus flowed away from the duct. For several days there was a sero-purulent discharge but the pain and swelling rapidly subsided.

The patient remembered getting a feather into her mouth whilst shaking a feather mattress and trying to spit it out. It must have slipped between the gum and the cheek, the end getting accidentally impacted in the opening of Stensen's duct. The movements of the cheek in eating would probably help it in its passage along the duct. The organisms producing suppuration would be introduced along with the feather from the cavity of the mouth.

Nottingham.

A CASE OF DEAD TWIN RETAINED TO FULL TERM.

By WALTER C. HEARNDEN, M.R.C.S. ENG., L.S.A.

ON March 2nd I was sent for to attend a multipara, thirty-two years of age. On arrival I found that a healthy girl, weighing 7 lb., had been born about twenty minutes and the placenta had been expelled naturally. The nurse produced a small dead fœtus which had come away with the placenta. It measured 3½in. in length when fully extended and the occipito-frontal diameter of the head measured 1⅛ in. It had been squeezed quite flat so that the body was not more than ¼ in. thick and the head was still less. It was enclosed in a membrane which could be peeled off it, but the fluids had escaped. There were a small placenta and an umbilical cord 1¼ in. in length. The head was rotated backwards and the spine folded down. The mother, whose last child is six years old, is very delicate, suffering from apex systolic murmur and floating kidney. She complained of great pain in the uterus during the pregnancy and was at times unable to get out of bed for days together.

TEDDINGTON COTTAGE HOSPITAL.

A CASE OF CÆSAREAN SECTION.

(Under the care of Mr. R. A. CLARKE.)

CÆSAREAN section has always possessed a great fascination for the popular mind, and to this fact must be attributed the numerous accounts which exist of its having been the means of ushering into the world several celebrated persons, though in most of the cases the tradition has very little foundation. Yet it is probable that the operation has a high antiquity, though no very trustworthy account is of earlier date than the commencement of the seventeenth century. The operation has been performed in a large number of cases of difficult labour, but unfortunately it has on the whole been accompanied by a very heavy mortality. At one time the mortality after the operation in England was calculated at over 85 per cent., though some allowance must be made for the desperate condition of many of the patients on whom the operation was performed. In 1874 Schroeder collected 480 cases of this operation in England, and of these 244 were fatal, a mortality of 50·8 per cent., and his figures for other countries did not materially differ from these. In more recent times the death-rate has decidedly diminished with the general employment of the antiseptic method; and Dr. R. P. Harris[1] has shown that during the eight years from 1886 to 1894 of 60 Cæsarean operations in the British Isles only 19 women died. This gives a mortality of 31·6 per cent. But results far superior to these have been obtained in the practice of some operators; for instance, Murdoch Cameron[2] of Glasgow had only 1 death in 10 cases, a death-rate of 10 per cent.

[1] THE LANCET, May 19th, 1894, p. 1242.
[2] Brit. Med. Jour., March 7th, 1891, p. 512.

Münchmeyer[3] has recorded that of 28 cases at Dresden only 3 proved fatal; this gives a mortality of 10·7 per cent.; and Paul Zweifel lost 2 cases out of 30, a mortality of only 6·6 per cent. That there is very little in the operation itself to account for the heavy death-rate which has usually accompanied it is shown by the fact that at least 6 cases are on record in which the patient has operated on herself, and in 5 of these she has recovered[4]; the most remarkable of these cases was recorded in THE LANCET in 1886.[5] The operation is also practised by the natives of Uganda, and with much success.[6] With such varying results the causes of the heavy mortality which so often follows the operation need to be investigated. They are chiefly these: hæmorrhage, sepsis, and exhaustion. The use of sutures for the uterine wall was introduced in 1769 by Le Bas of Mouilleron,[7] yet many operators declined to insert sutures into the wall of the uterus for more than a hundred years later; if they are employed hæmorrhage need not be feared. Sepsis is naturally less common now than formerly, but it is noteworthy that long before the introduction of the antiseptic method the mortality after Cæsarean section in the hospitals of large towns was always much greater than in cases operated on in the country. Dr. R. P. Harris has shown that in the United States the death-rate in the country was only 37·5 per cent., while in small towns it was 66 per cent. and in large cities 67 per cent., and the same fact has been noticed in England. The explanation undoubtedly is that at that time there was a much greater risk of sepsis in a hospital than in a country cottage. The third cause of death—namely, exhaustion—is less easy to evade than the two others, for there is a very natural tendency to postpone such an operation until all other modes of delivery have been tried. When compared with other methods Cæsarean section probably does not give results superior to craniotomy if the operator is a skilled obstetrician, but for the average medical man in country practice we think that the Cæsarean operation offers a better prospect of a successful result. In this sketch of the operation we have not considered the question of the child, for it is generally recognised that the life of the mother is the first consideration. At least two cases are recorded in which Cæsarean section has been performed with success four times on the same individual.[8] We cannot but think that in time Cæsarean section will be attended with a much lower mortality and that it will in great part replace craniotomy in cases of difficult labour. In Mr. Clarke's very interesting case it is extremely doubtful if a successful result would have followed any other method of treatment.

On Feb. 16th last, Mr. Clarke having been called to see the patient in consultation with a neighbouring practitioner, was informed that she had been in labour for about 40 hours and on examination he found a right foot and left hand presenting externally; the cord was prolapsed and in the brim could be felt the other hand and lower half of the face, the forehead being firmly impacted on the pubes. Repeated attempts had been made to perform podalic version, by which the presenting leg had been broken, and the jagged ends of the tibia and fibula looked decidedly dangerous; unsuccessful attempts had also been made to grasp the head with forceps and by this time the mother's parts had become intensely swollen and œdematous, the uterus being in a state of strong tonic contraction. Her surroundings from a sanitary point of view being simply deplorable she was removed to the Cottage Hospital before anything further was attempted. On arrival there a consultation was held and as she was in a very exhausted condition a subcutaneous injection of liquor strychninæ was administered and she was at once placed under an anæsthetic. On making a full and careful examination the fœtus was found to be so firmly impacted that it was impossible to move it or to alter its position, and as it lay no part of the head could be reached to perforate without extreme difficulty. Evisceration was practically impossible. As the woman was now showing urgent signs of exhaustion it was decided that Cæsarean section would be the quicker and safer method of delivery, and this Mr. Clarke did at once, removing the fœtus without difficulty. The placenta was not adherent and hæmorrhage was very slight. After thoroughly douching the uterine cavity with water at 120° F. and suturing the uterine incision with six points of stout silk, the abdominal wound was closed with six deep sutures of silk and ten superficial ones of horsehair; a good dusting with iodoform, a pad of blue gauze, and a flannel roller completed the dressing. The patient was now put to bed in a very exhausted condition but she gradually improved. Twelve hours later her temperature was subnormal and it rose slowly until the third day, when it reached 100·2°. It declined to normal by the eighth day. The wound healed by first intention and the recovery was uneventful. At the time of writing (35 days after operation) the patient is up and walking about the ward, apparently none the worse, only wearing a belt as a precautionary measure.

Remarks by Mr. CLARKE.—Contracted pelvic brim being the usual condition which necessitates Cæsarean section, the present case is of special interest as the patient was a multipara, twenty-five years of age, with a normal and full-sized pelvis. I have refrained from giving details of the operation or after-treatment, my only object in writing being to show that Cæsarean section in given cases is a much safer proceeding than protracted attempts at evisceration or perforation, which must often result in severe damage to the uterus and vagina.

SHEFFIELD ROYAL HOSPITAL.

A CASE OF PULMONARY ABSCESS SUCCESSFULLY DRAINED.

(Under the care of Dr. DUNCAN BURGESS and Mr. SINCLAIR WHITE.)

THOUGH pulmonary abscesses have been opened with success in no small number of cases, yet many surgeons hesitate to perform the operation unless the abscess is almost pointing externally. It is true that in many cases which are tuberculous in origin the relief afforded by the operation is only temporary, as the case goes on to its fatal issue, but the relief is often very great. True[1] quotes several cases in which the operation has been successful, and Réclus[2] collected 8 cases in 6 of which recovery resulted. For the notes of the case we are indebted to Mr. Sinclair White.

A woman, aged twenty-five years, was admitted to the Sheffield Royal Hospital on Aug. 13th, 1897, under the care of Dr. Duncan Burgess, who subsequently handed the case over to Mr. Sinclair White. The history was briefly as follows. Three years previously she had an attack of spitting of blood and was said to be in danger of developing phthisis. She then remained well and free from lung trouble for two years. In October, 1896, the spitting of blood returned and continued at intervals for the succeeding three months. From this time onwards until she was operated on she never lost her cough. In March, 1897, she again spat blood, but she was able to go about until June when her cough became very troublesome and for the first time she noticed that the expectorated matter had an offensive odour.

On admission to hospital the patient was moderately emaciated. She had a very troublesome cough and expectorated a large amount of offensive sputum. Microscopical examination of sputum revealed an abundance of pus corpuscles, but no bacilli of tubercule could be detected. The temperature increased to 103° F. in the evening and she had night sweats and hectic. The lower half of the left side of the chest was dull on percussion and vocal resonance and fremitus were diminished. The heart was not displaced. An aspirating needle revealed clear serum at about the depth of the pleura over the affected region. The case was watched until Dr. Burgess returned from his holiday, when he diagnosed a pulmonary abscess and requested Mr. Sinclair White to drain it.

An operation was performed on Sept. 14th, when the patient was placed in the left semi-prone position with the left side of the chest close to the edge of the table. The left eighth and ninth ribs were resected just beyond their angles, about one inch of each rib being removed. The pleura was then carefully opened, when a small quantity of clear serum escaped. On introducing the finger Mr. Sinclair White ascertained that he had got into a detached portion

[1] Essai sur la Chirurgie du Poumon (Paris, 1883).
[2] Transactions of the French Surgical Congress, 1895, in Appendix to S. Paget's Surgery of the Chest.

of the pleura completely shut off from the general pleural space. The lung, covered with glistening pleura, could be seen at the bottom of the opening. An aspirating needle was thrust into the centre of the portion of the lung exposed and at the first attempt pus was found. Leaving the needle for a guide Mr. Sinclair White passed a sharp-pointed bistoury along its course and after traversing half an inch of hepatised lung tissue it entered the abscess cavity, which was approximately 2 in. by 3 in. in extent and irregular in outline. No attempt was made to cleanse the cavity, but a large rubber tube was inserted and was surrounded with iodoform gauze where it passed through the pleura. The operation was well borne and there was very little hæmorrhage from the lung.

From the date of the operation the patient steadily improved. The evening fever, hectic, and sweating at once disappeared and the cough became less troublesome. The discharge rapidly lost the evil odour it had at first possessed and gradually diminished in amount. The tube was replaced by gauze at the end of six weeks and a fortnight later the wound had entirely healed. She was discharged at the end of November in robust health, having gained much flesh and entirely lost her cough.

Remarks by Mr. SINCLAIR WHITE.—The case was a suitable one for operation and gave rise to no surgical difficulty. In the majority of cases of pulmonary abscess which come under the care of surgeons it would appear that the pleural space over the affected region is obliterated by antecedent inflammatory exudation. In such cases the surgeon's task is a simple one. But when the pleura over the affected part of the lung is not obliterated the difficulties and dangers of the operation are greatly increased. At present it would seem that the safest way of dealing with such cases is to divide the operation into two stages with an interval of four or five days. The first stage consists in cutting down to the pleura and passing a ring of sutures through its parietal and visceral layers so as to isolate the area of operation from the rest of the pleural space. The wound is then packed with gauze and as soon as the effused lymph has sealed off the "operation area" the lung is incised. The semi-prone position on the affected side is undoubtedly the most suitable one for operation. It permits of free play for the healthy lung and gives free access to the back of the diseased lung, while it reduces the risk of suffocation from pus suddenly entering the sound lung on opening a large abscess.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Immunity from Cobra Poison.—Molluscum Contagiosum in Sparrows.—Adenochondroma of the Submaxillary Gland.—Primary Myxo sarcoma of the Pleura.—Primary Sarcoma of the Lung.—Myxœdema.—Exhibition of Specimens.

A MEETING of this society was held on April 5th, the President, Dr. J. F. PAYNE, being in the chair.

Dr. WALTER MYERS (Cambridge) read a preliminary note on some experiments bearing on Immunity against Cobra Poison. Dr. Myers first reviewed the different views which were held as to the nature and mode of action of antitoxins. He supported the view that a certain amount of the antitoxic substance was normally present in the animal which furnished the antitoxin and that this chemically combined with and neutralised the toxin. He referred to the experiments of Wassermann, who showed that if the brain of a guinea-pig were intimately mixed with tetanus toxin the latter became neutralised in vitro and inert when injected unless an excess of toxin were present. Dr. Myers's own experiments had been undertaken with cobra poison. He tried to find out whether any of the organs of the guinea-pig had any antitoxic effect on the poison. He found that the brain and spinal cord had no effect and the only organ which gave positive results was the suprarenal body. He used a 10 per cent. emulsion in sterilised normal saline solution. He used rather more than the ordinary lethal dose of the toxin and mixed it with the suprarenal emulsion before injection. Seven animals were injected and of these four survived altogether and the remaining three lived much longer than the "control" animals. Positive results were also obtained from the suprarenal body of the sheep, two out of three of the animals experimented on recovering.

Mr. S. G. SHATTOCK exhibited specimens of Molluscum Contagiosum in two mated Bunting Sparrows. In November, 1897, a bunting sparrow was sent to the Royal College of Surgeons of England with a spheroidal tumour under the mandible, which was found on histological examination to be in all details a molluscum contagiosum as this is met with in the human subject, the typical molluscous bodies occurring in the epithelium, arranged in the well-known acinoid groups. The molluscous material was not chemically identical with the eleidin of the stratum granulosum. About a month later the mate of this bird was sent to the College, a similar swelling having developed in it after the death of the first sparrow. The growth in the second case lay in front of the left eye and likewise presented the histological appearances diagnostic of molluscum. Circumstances rendered it as probable here that the disease had been contracted in the second bird by inoculation, as did the clinical evidence that the disease was contagious in the human subject. Mr. Shattock did not see how dermatologists could question its contagious character. He had examined molluscum in the sparrow, but it was especially in fowls, turkeys, and pigeons that the disease occurred, the lesions being commonly about the head owing to the fact that this was the least protected part and the most exposed to inoculation by reason of the well-known habits of birds, whether of amorous or vindictive kind. He had been unable to discover whether the disease was present amongst those to whom the birds belonged. Mr. Hutchinson had recorded a unique instance in which molluscum was present in a dog (as proved by microscopic examination) and in its owner and in which the latter appeared to have contracted the disease from the former. As to the protozoic nature of the molluscous bodies this was still *sub judice* and until Koch's second postulate was carried out no statement in this regard could be held as anything else than an opinion. He referred to the comparatively simple attempts in this direction made by Mr. Ballance and himself, which gave a negative result. As damp sand and pond water were the natural habitats of the common amœba, and as psorospermiæ flourished so widely in the fresh water of ponds and rivers, wet sand was the medium selected. After complete sterilisation the sand was placed in capsules and heaped up to one side, so that when the sterilised water was added part of the sand remained above the water level, the object of which was to obtain a littoral for the better aeration of any protozoa that might develop. Freshly excised mollusca were divided and pushed into the wet sand, the latter being subsequently examined from time to time by withdrawing portions from the neighbourhood of the fragments; no evidences of protozoic life were ever encountered.—Dr. COLCOTT FOX said that the disease was not very uncommon among fowls and sometimes took the form of a destructive epidemic. Yaws had been described as occurring in fowls in the West Indies. A friend sent him home specimens of supposed yaws in a fowl, but on examination the disease turned out to be molluscum contagiosum.—The PRESIDENT did not think that it was doubted in this country that the disease was contagious, although it did not pass very readily from man to man. It was probable therefore that it carried on its life in its most certain and most prolific form in the lower animals, especially poultry.

Mr. H. J. CURTIS exhibited a specimen of Adenochondroma of the Right Submaxillary Gland. The case occurred in a woman, twenty-four years of age, under the care of Mr. A. E. Barker. The growth had been noticed for eight or nine years and three years before the patient came for advice it had begun to increase in size gradually. The tumour formed a swelling below the middle of the right superior maxilla. It was very hard and of the size of a walnut. It moved freely beneath the skin, but from its deep surface a process could be felt extending inwards. It could also be felt in the mouth and made still more prominent there by external pressure. The patient was perfectly well and free from recurrence nine months after removal of the growth. The tumour was enclosed in a firm fibrous capsule and was nodular. On section numerous pearly-white cartilaginous-looking patches were seen scattered over the cut surface, which was otherwise of a light buff colour. Microscopically hyaline cartilage with immature stellate cells pervaded the whole growth, the cartilage columns being separated by solid cylinders of cubical epithelium, which also appeared as tubular acini. In some of the tubules secretion was clearly visible. Referring to the literature of the

subject, after careful search Mr. Curtis found that some 11 or 12 cases have been recorded on the continent and, including the present specimen, 9 by English observers. The benign nature of this tumour, so much more commonly seen in the parotid, was referred to in connexion with prognosis and the need for the careful record of every case was emphasised so as to obtain a more accurate estimate of the frequency with which it occurs.

Dr. PERCY KIDD and Dr. S. H. HABERSHON showed a specimen of Primary Myxo-sarcoma of the Pleura. The patient, a girl, aged eighteen and a half years, was admitted into the Brompton Hospital on Sept. 1st, 1897, for pain in the left side and dyspnœa which had set in suddenly a month previously. On admission there were physical signs of a large effusion into the left pleura, the heart being greatly displaced to the right. But at first it was noted that although the dulness in front extended from apex to base posteriorly the dulness did not reach higher than the middle of the scapula. Subsequently the whole left side became dull to percussion and the dulness extended across the upper part of the sternum to the right as far as the mid-clavicular line. There were no enlarged glands and no paralysis of the vocal cords. The temperature only once rose above 100° F. Paracentesis was performed on four occasions, but only a little blood was obtained. Dyspnœa and exhaustion increased and the patient died on Oct. 29th, 1897, three months after the onset of her illness. At the necropsy an enormous mass was seen filling up the left chest and extending across into the right side, the heart lying entirely to the right of the sternum. The left lung lay collapsed and carnified behind the tumour, the pleural cavity being obliterated by spongy adhesions. On section the tumour consisted of a coarse fibrous network enclosing many large blood cysts, a smaller number of cystic spaces containing viscid puriform matter and some yellowish-white masses of growth. The lungs, mediastinal and bronchial glands were unaffected and there were no secondary deposits in the body. The softened puriform material consisted microscopically of stellate and pyriform cells with a few pus corpuscles. Sections of the solid growth presented the characters of a myxo-sarcoma with extensive hæmorrhages and numerous large thin-walled vessels.

Dr. HABERSHON also showed a specimen of Primary Sarcoma of the Left Lung from a man, aged seventy-eight years. In its clinical aspects the case was one of importance because it presented the physical signs of an empyema with considerable contraction of the left side and displacement of the heart almost to the axilla. It is always a point of difficulty to decide how far contraction of the affected side is compatible with a malignant growth, and though the case is not an isolated one the condition is by no means common. The growth was a primary sarcoma occupying the position of the centre of the lower lobe of the left lung, softening and ulcerating its way into the œsophagus. The surrounding lung was indurated and in an advanced state of fibrosis.

Mr. CECIL BEADLES gave a very complete demonstration from lantern slides of the microscopic changes of the Thyroid Body, the Pituitary Body, the Skin, the Muscles, and the Adipose Tissue from two cases of Myxœdema. In the second case there were also trichinæ in the sterno-thyroid and pectoral muscles. There was insanity in each case. The chief points shown were the atrophy of the thyroid, enlargement of the pituitary, and a pale gelatinous condition of the fat. The nuclei of the fat-cells were vacuolated. In the lungs there were nodules of dense hyaline material the nature of which was uncertain.

The following card specimens were exhibited:—

Mr. PERCY FURNIVALL: Fœtus showing a Hernia.

Dr. ROLLESTON: Pancreatitis.

Mr. G. T. JAMES: (1) Subdural Hæmorrhage; and (2) Pyosalpinx.

Dr. HEBB: Peri-œsophageal Cyst.

HARVEIAN SOCIETY OF LONDON.

The Treatment of Caries of the Spine.

A MEETING of this society was held on March 31st, Mr. J. H. DREW being in the chair.

Mr. JACKSON CLARKE said that in its main features tuberculosis of the spine might be compared with a similar condition in a large joint. Radical treatment in the form of complete excision of the diseased parts had been practised even in the spine, but the usual means adopted were: (1) Rest on a firm mattress in a supine position with or without weight-extension; (2) Phelps's box; (3) the double Thomas's splint; (4) Sayre's plaster jacket; (5) the felt corset; and (6) steel splints, which might be combined with rest on a prone couch. Whenever symptoms pointed to rapid progress of the disease rest with weight-extension was indicated. In less rapid conditions Mr. Clarke preferred a good steel splint to any form of corset. Chance's (1852) and Taylor's (1871) were the best known of the steel supports. In principle they were closely allied. Mr. Clarke used the older of these instruments and found it very satisfactory, as it admitted of readily-effected modifications in cases of cervical and high dorsal caries. Combined with rest on a prone couch, Chance's splint could be used successfully even in unpromising cases. The chief complications were (1) abscess, (2) sinus, and (3) paraplegia. Mr. Clarke related a case in which a psoas abscess had ruptured, causing a diffuse suppuration in the thigh. Since antiseptics had removed the objections to early opening of abscesses there was now no need of delay when once the condition had been recognised. Sinuses need only be feared when abscesses opened spontaneously, and even when of old standing they could often be made to close by injecting daily one or two drachms of 1 in 40 carbolic lotion. When profuse suppuration persisted or lardaceous disease threatened sinuses might demand operative measures. With regard to paraplegia he had seen even hopeless-looking cases recover without operation, and in every case he would give rest a prolonged trial before contemplating surgical interference. Laminectomy was indicated in many cases of fracture of the spine, but fracture was of rare occurrence in caries, and on *a priori* grounds it would appear undesirable to remove the remaining sound parts of the spinal column opposite the seat of disease. Immediate reduction of the angular deformity had in several cases of paraplegia appeared to do good and it might certainly be tried as an alternative to laminectomy.

Dr. JAMES TAYLOR said that on post-mortem examination paraplegia had been found to be associated with myelitis. He agreed that with prolonged rest most cases would do better than with operation.

Mr. DREW remarked that he was glad to find that the spinal support shown at the meeting could be successfully substituted in suitable cases for the unyielding plaster of Paris and felt jackets, also that there was an absence in the support of "iron crutches" in the axillæ and the adoption of a padded strap which was equally effective and far preferable. Mr. Clarke was to be congratulated on the good result of the cases he had brought before the society.

Mr. HUBERT PHILLIPS stated that he had, both as a student and in private practice, had excellent results from the application of Sayre's jacket, always in mild cases, however. He had invariably used extension in order to relieve pressure on the diseased portion of the spine and also to obtain good support from the armpits. The Sayre jackets were, however, at best uncomfortable appliances to wear, owing to the length of time patients were obliged to keep them on. Chance's splints certainly had many palpable advantages. He asked Mr. Clarke at what period of the disease Chance's splints should be applied and what was the earliest stage at which it was advisable to start using them?

Dr. WINSLOW HALL urged the value of prolonged recumbency and was surprised that in many cases Mr. Clarke allowed the patient to walk about.

Mr. JACKSON CLARKE replied that Sayre's jacket sometimes gave temporary relief, but it failed to check the progress of the disease. Prolonged recumbency was necessary in many cases but the benefit derived from it was sometimes lost by its being persevered in too long. The steel splint was the lightest form of apparatus and he used it for children from two years of age and upwards as well as for adults.

OBSTETRICAL SOCIETY OF LONDON.

The Menstruation and Ovulation of Monkeys and of the Human Female.—Exhibition of Specimens.

A MEETING of this society was held on April 6th, Dr. C. J. CULLINGWORTH, President, being in the chair.

Mr. WALTER HEAPE read a paper on the Menstruation and Ovulation of Monkeys and of the Human Female. 1. Menstruation.—Mr. Heape described the histological process of menstruation in Macacus rhesus as identical with that already described in the society's Transactions for Semnopithecus entellus—viz., a growth of stroma and increase of vessels, a breaking down of congested vessels and consequent formation of lacunæ, a degeneration of the superficial mucosa and rupture of lacunæ, and a denudation of the superficial portion of the mucosa with consequent formation of a menstrual clot—the only difference of moment being that in Macacus rhesus the mucosa is thicker, the protoplasmic network is denser, and the glands are more numerous and more branched than in Semnopithecus entellus. Sections of human and monkeys' uteri were shown to demonstrate these points and Mr. Heape was led to infer that in all probability the menstrual process is practically identical in women and in female monkeys. He pointed out that although monkeys menstruate all the year round they (at least some of them) only breed at certain times of the year and thus occupy an intermediate position between the lower mammals and the higher primates. He expressed the opinion that the histological homology of "heat" and menstruation would be established. 2. Ovulation.—With regard to the relation between ovulation and menstruation two divergent views were quoted, the one that ovulation occurs at each menstrual period and that the two processes are due to the same active cause; the other that ovulation and menstruation are independent of each other, that they are due to independent stimuli and are coincident only by accident. Out of 59 adult menstruating female monkeys only one was found with a recently discharged Graäfian follicle. Mr. Heape summarised his observations by stating that in women and female monkeys (1) ovulation and menstruation are not necessarily coincident; (2) menstruation may take place without ovulation; and in women (3) ovulation may occur without menstruation. Mr. Heape combated the views that in the lower animals "heat" is brought about by ovulation or that the ovary is the seat of the stimulus which induces heat; he urged that both menstruation and ovulation are closely connected with, and largely influenced by, congestion, and that in the primitive condition they were both due to the same cause.

Dr. PETER HORROCKS said that in women there was incontestable evidence that ovulation occurred without menstruation, for it was a well-known fact that a woman might conceive without menstruating. Girls in India not infrequently conceived before menstruation began and a woman during the amenorrhœa associated with lactation occasionally conceived again without menstruating. He did not, however, know any facts which proved that menstruation could take place without ovulation. It was well known that when the ovaries were removed, or if they became wholly degenerated, or if they ceased their function, then menstruation ceased. He could not help feeling that menstruation in women and rut in animals were not the same thing.

Dr. HERMAN thought that Mr. Heape's valuable paper went to show how very imperfect our knowledge was of the physiological changes that went on in the ovary. He still thought that menstruation depended, if not upon ovulation, yet upon some ovarian function; he based this opinion upon the broad clinical facts that when the ovaries were absent or ill-developed menstruation was never present and when both ovaries were removed menstruation always stopped.

Mr. HEAPE replied.

The following specimens were exhibited:—

Mr. DAWSON: A Uterus with Ruptured Tubal Gestation Sac in which the pregnancy had not advanced beyond the fifteenth day and which terminated fatally from hæmorrhage.

Dr. MACNAUGHTON JONES: A Uterine Fibroid with anomalous Solid Ovarian Tumour.

Dr. WALTER TATE: A Fibro-myoma of the Uterus removed by abdominal hysterectomy.

The PRESIDENT made reference to the recent death of Dr. Leonard Remfry, assistant obstetric physician to St. George's Hospital, and of Dr. Charles West, a past-president and an honorary Fellow of the society, and it was agreed that suitable letters of regret and condolence should be forwarded in the name of the society to Mrs. Remfry and to Mrs. West.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

The Use and Abuse of Mydriatics.—Morphia in Cardiac Diseases.—Coley's Fluid in Sarcomata.

THE sixth meeting of the forty-second session of this society was held on April 1st at the Royal Kent Dispensary, Greenwich-road. The chair was occupied at first by Dr. MORGAN DOCKRELL and afterwards by the President, Mr. W. ARBUTHNOT LANE.

Mr. ERNEST CLARKE read a paper on the Use and Abuse of Mydriatics. He enumerated the various mydriatics in common use and after describing their physiological action and their individual peculiarities he specially drew attention to the great value of homatropine and cocaine as a paralyser of the ciliary muscle when used sufficiently strong. By experiments on himself and others he had obtained complete loss of accommodation in thirty-five minutes with a tabloid of homatropine and cocaine gr. $\frac{1}{10}$, and the great advantage of this drug was that all effects had passed off in twenty-four or twenty-six hours. He detailed the different uses of mydriatics and showed that the most important result of their use was "putting the eye into splints." He further showed why they were so dangerous in acute glaucoma and finally very strongly recommended the use of ophthalmic discs or tabloids, which on account of their accuracy, non-liability to decomposition, and the fact that toxic effects rarely, if ever, followed their careful use, rendered them far preferable to drops and lotions.

Dr. F. S. TOOGOOD, Medical Superintendent of Lewisham Infirmary, read a paper on the Use of Morphia in Cardiac Disease, and after describing the physiological effects of the drug upon the cardio-vascular system and upon the kidneys recounted a series of cases in which perfect compensation of the heart and entire cessation of all symptoms had been obtained after the failure of all other drugs, including digitalis and its allies, which had only excited persistent and uncontrollable vomiting. The paper drew special attention to the fact that scanty urine containing albumin was an indication for the administration of morphia and gave many instances where its use had been accompanied by the secretion of the normal amount of urine and by the total clearing up of the albumin.

Dr. MORGAN DOCKRELL read a short paper on the Use of Coley's Fluid in Sarcomata and described the results in a case under his care.

The several papers were discussed by the PRESIDENT, Dr. TAYLOR, Dr. SCHOLEFIELD, and Dr. DOCKRELL.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Clinical Report of the Rotunda Hospital.—Exhibition of Specimens.

A MEETING of this section was held on March 18th, Dr. F. W. KIDD, the President, being in the chair.

Dr. W. J. SMYLY read the Clinical Report of the Rotunda Hospital for three years, 1893-96.—The PRESIDENT said that the thanks of the section were due to Dr. Smyly and his collaborators, Dr. Wilson and Dr. Jellett, for the report. He thought such results were not likely to be eclipsed for a considerable time. He expressed surprise at the number of cases under the heading of Accidental Hæmorrhage. In 134 cases of abortion 50 were curetted, which seemed to be a very large proportion. He congratulated Dr. Smyly on there being no death from placenta prævia. He thought that severe post-partum hæmorrhage, not arising from the situation of the placenta at all, often occurred and that its origin was often overlooked. He thought that the case in which there was found a double uterus after removal of the uterus and the subsequent recovery of this patient was very remarkable.—Dr. TWEEDY observed that a great many of the deaths were in women brought into the hospital with fatal symptoms already marked. Three of the five septic cases had evidently become septic outside and nothing could have saved them. The cases of eclampsia seemed to have been very severe. The giving of morphia in eclampsia was an interesting point. Some observers say that its administration kills the child, but in one of Dr. Smyly's cases the child

was alive although the mother got more morphia than any other case.—Dr. LANE said that he could not quite agree with the President's opinion that the deaths from accidental hæmorrhage were above the average.—Dr. GLENN remarked that the use of the sharp curette in the treatment of abortions was in skilled hands quite safe, while for those not so self-confident the use of the blunt instrument was good practice. Dr. Smyly's three fatal cases of incomplete abortion would have died whether curetted or not. He thought that a serious omission in reference to forceps cases had been made in the report—viz., there was no record of mortality in regard to the children. He thought that a record of these deaths should also be kept as it would be of great interest to future generations.—Dr. SMYLY, in reply, said that if the suggestions made by Dr. Glenn were adopted by future reporters they would add to the value of future reports. He would himself suggest that in addition to noting the total number of cases in which the temperature rose above 100·8° F. it would be important to record the number of cases in which the patients were really ill and those in which it rose on one occasion only.

Specimens of Myomatous Uteri, Ovarian Cysts, and Ovarian Sarcoma were shown by Dr. SMYLY, Dr. J. H. GLENN, Dr. R. D. PUREFOY, and Dr. JELLETT.

ULSTER MEDICAL SOCIETY.

Management of Labour.—Life Insurance.—Exhibition of Specimens and Cases.

A MEETING of this society was held in Belfast on April 7th, the President, Dr. J. A. LINDSAY, being in the chair.

On the motion of the PRESIDENT, seconded by Professor BYERS, it was unanimously agreed to send a letter of condolence to the widow of Dr. Henry Bingham, a well-known member of the society, whose death had occurred since the previous meeting of the society.

Professor BYERS read a paper on the Management of the Third Stage of Labour. He said that there were two factors to be considered in the third stage of labour: (*a*) the separation and (*b*) the expulsion of the placenta and membranes, and it would be necessary to examine how nature herself managed this period. He then discussed the various theories put forward to account for the separation of the placenta—viz., the retro-placental hæmatoma view, the detrusion theory, and the view that separation of the after-birth is due to a disproportion in size between the placental site (where it is attached to the uterus) and the placental area (placenta itself). In the settlement of this question they must be guided by evidence afforded from two sources: clinical experience and sectional anatomy. Professor Byers pointed out the special value of the sectional anatomy of the third stage of labour and showed that the original observations in this direction made by Dr. Barbour of Edinburgh had been fully confirmed by Pestilozza of Milan, Stratz of Berlin, and Pinard and Varnier of Paris. It had thus been demonstrated that the placenta did not separate until the third stage of labour, that its area could contract to almost one-half its size without separation taking place, that there was no hæmorrhage behind the placenta, and that there was no cavity in the uterus beyond that occupied by the after-birth. In the management of the third stage of labour some had urged an expectant plan until nature herself expelled the placenta; others (Ahlfeld) advised waiting two hours. The objections to this treatment were stated and Credé's method and the "Dublin" plan were very fully described and contrasted. Professor Byers said they must try to allow the placenta to be separated by the uterus itself, and it was when this had occurred and when the upper, thick, active, contracting portion of the uterus had driven the placenta into the lower uterine segment (which was expansile and passive) or vagina that pressure from above the axis of the brim should be made to expel the afterbirth. He pointed out how they could ascertain clinically that there was separation of the placenta. In most cases the uterus by its retraction and contraction effected this itself; in a few cases gentle massage was necessary. In conclusion he recommended as the best way of conducting the third stage of labour: (*a*) following down the uterus when the fœtus was being expelled; (*b*) the constant control of the uterus by the hand; (*c*) the turning of the patient on her back after the birth of the child; (*d*) waiting, if possible, for nature to separate the placenta; (*e*) then expression of the afterbirth; and (*f*) the continued control of the uterus with the hand until the binder was applied.

Dr. W. CALWELL read a paper on Moot Points in the Medical Examination of Cases for Life Insurance. He discussed very fully the best methods of examination and some moot points in their bearing on life insurance, as heredity, hæmoptysis, proclivity to infectious diseases, intemperance, smoking, heart disease (murmurs, tension and rapidity of pulse), syphilis and gonorrhœa, appendicitis, and albuminuria.—The following members spoke on the above papers: Mr. MCFARLAND, Dr. KEVIN, Dr. STOREY, Dr. FULLERTON, Surgeon-Major PIKE, Professor BYERS, and the PRESIDENT.

The following specimens and cases were exhibited:—

Mr. T. S. KIRK: Two cases of Fractured Olecranon treated by immediate suture.

Mr. ROBERT CAMPBELL: Skiagram from a case of Club Hand with absence of the Radius.

Dr. W. CALWELL: A man who, as the result of an accident, had developed Heart Disease and wasting of the Muscles of one Thigh.

Reviews and Notices of Books.

Memory and its Cultivation. By F. W. EDRIDGE-GREEN, M.D. Durh., F.R.C.S. Eng. London: Kegan Paul, Trench, Trübner, and Co. 1897. Price 5*s*.

THIS book, which forms one of the volumes of the International Scientific Series, deals with a subject of considerable interest in a manner at once clear and reasonable. Dr. Edridge-Green employs a physiological basis for his analysis of memory, which he divides into "sensory" and "motor," whilst his discussion of the "faculties of the mind" based, as it avowedly is, on the phrenological systems is interesting but perhaps somewhat liable to misinterpretation. It may be questioned whether it is strictly correct to establish so many various "faculties" as is here done. Chapters on "Remembrance, Recognition, Recollection," "The Direct Connexion between the Motor and Sensory Memories," "Memory in the Lower Animals," "The Variations of Memory at Different Periods of Life," "Some Anomalous Conditions in which Memory plays an Important Part," "Pathological Conditions in which the Memory is Affected," and the "Localisation of Memory" lead up to the formulation of definite rules for the cultivation of memory, which constitute the second part of the book. We may quote his conclusion as to localisation which strikes us as being somewhat absolute. He says (p. 250): "All sensory impressions, whether elaborated by the faculties of the mind situate in the cerebral hemisphere or by the sensory nerves, are permanently stored up in the optic thalami and constitute the sensory memory. All voluntary motor impulses, whether discharged on account of information derived from the sensory memory or when the equilibrium has to be maintained in a large part through a special source, the cerebellum, leave a permanent modification of the cells and fibres of the corpora striata, constituting the motor memory. After the faculties have discharged their functions in establishing the sensory and motor memories and the latter have reached the necessary intensity, they become directly combined and act, in a large part, irrespective of the consciousness of the individual when the appropriate stimuli are applied."

As regards the "cultivation of memory" many a man now of middle age may recall the schoolday instructions by teachers of "mnemonics," with some degree of scepticism as to the value of such instruction in facilitating the learning of subjects, whilst in his later career as a student he may

have had many a "memoria technica" impressed upon him as an aid to the recollection of anatomical relations and facts. Dr. Edridge-Green proceeds on a more scientific method, and gives his readers much valuable advice in expounding the twenty-two rules which he here formulates as of value to the strengthening of the memory. We presume that as a matter of fact most of us pursue these paths in our daily reference to the storehouse of facts and ideas which are associated one with another in our minds; but it is nevertheless not superfluous to have the prescribed methods of recollection systematised and explained in the lucid manner of the author. Indeed, we can well believe that few can carefully read this part of the book without a sense of greater security in the use of that most treacherous of instruments, the memory. We can heartily commend this book for perusal, as being both profitable and stimulating.

The Royal London Ophthalmic Hospital Reports. Edited by WILLIAM LANG, F.R.C.S. Eng. London: J. & A. Churchill. December, 1897. Vol. xiv., Part iii.

THE establishment of the Ophthalmological Society and the publication of the reports of that society have acted prejudicially on the reports of the Royal London Ophthalmic Hospital, for whereas the earlier volumes contained accounts of most of the interesting cases which fell under the care of the surgeons of the Moorfields Hospital, of late years, as might naturally have been anticipated, the most striking forms of disease have gravitated to the Ophthalmological Society and have been shown or described at its meetings, whilst the reports upon them have been impounded by the active secretaries, and have contributed to the value of their yearly volume. Still there are gleanings to be obtained by diligent workers even in the most carefully raked field, and we have the outcome of such gleaning in the present part of the fourteenth volume. It contains the following articles: 1. An Account of a Case of Metastatic Carcinoma of the Eyeball, by the curator of the museum of the Hospital, Mr. C. Devereux Marshall. The author appends a brief history of other cases which have been recorded, making a total of 30 eyes in 24 persons. In the majority of instances the primary growth was in the breast. As a rule it is noted that the tension of the globe was increased, but in a large number of cases it was normal. Although other organs are almost always involved Mr. Devereux Marshall recommends removal of the eye. 2. Concomitant Strabismus, the Accessory Adductors and Abductors, by Mr. J. Herbert Fisher. Mr. Fisher suggests reasons for believing that the superior and inferior recti aid in adduction, whilst abduction is effected by the external rectus and the two oblique muscles. 3. Notes on Glioma Retinæ, by Mr. C. Devereux Marshall. The cases reported include all that have occurred since those contained in the article written in the Hospital Reports by Mr. Lawford and Mr. Collins in 1890. Several of them have lived more than six years after the operation. The duration of life in fatal cases is given, and in addition the interval of time between the discovery of the growth and operation in fatal cases and cases of recovery, the site of recurrent growth, the shrinking of eyes affected with glioma, and the family history. The statistics of this and of the other articles by Mr. Marshall are remarkably well worked up and are very creditable to his industry. 4. The Operative Treatment of Lamellar Cataract, by Dr. E. C. Fischer, late senior house surgeon, and Mr. C. Devereux Marshall. The classification made by the authors is into two groups—(1) extraction and (2) needling—which they sub-divide into simple needling, needling followed by curette evacuation, and needling followed by section. It is interesting to note that simple needlings are by no means free from risk of suppuration, 8 eyes suppurating out of 123 operations, whilst 1 eye was excised for slow suppurative iritis in a case of needling followed by curette evacuation and 1 eye suppurated in a needling followed by suction, making in all 10 lost eyes in 260 operations, or a percentage of 3·84, a larger percentage than in needling after cataract operations, which only equal 1·02 per cent. 5. An Historical Review and Criticism of the Bacteriological History of Trachoma, with Personal Observations of Fifteen Cases, by Mr. Arnold Lawson—a very interesting article, giving the various opinions on the nature of the disease which have been maintained since the introduction of bacteriological investigation. Lastly, Mr. Devereux Marshall contributes a Descriptive Catalogue of Specimens in the Hospital Museum. The part contains also a Supplementary Catalogue of the Library of the Hospital.

LIBRARY TABLE.

A Manual of Botany. By J. REYNOLDS GREEN, Sc.D., F.R.S., F.L.S. Vol. II. London: J. and A. Churchill. 1898. Price 10*s.*—This excellent text-book on botany is based upon the well-known manual of the late Professor Bentley and this the second volume deals with the classification and the physiology of plants. In the first chapter the general principles which underlie the natural and artificial methods of classification are discussed. A short chapter is also devoted to the consideration of the individual systems and some of the more important ones, including those of Linnæus, Lindley, Bentham and Hooker, and others, are sketched out in tabular forms. The main part of this volume is devoted to the characteristics of the various classes and their sub-divisions, but a considerable amount of space has also been found for an interesting account of the general physiology of plant life. The book is well illustrated and will continue to take a high place among the text-books on this subject.

Analytical Key to the Natural Orders of Flowering Plants. By FRANZ THONNER. London: Swan Sonnenschein and Co. 1895. Price 2*s.*—This little book describes the principal features of the different orders of the flowering plants. The author has preferably chosen those characters which are visible to the naked eye at the time of flowering. The book is one which will no doubt be found useful by practical workers and should aid them considerably in the identification of plants.

The Principles of Bacteriology. By A. C. ABBOTT, M.D., Director of the Laboratory of Hygiene, University of Pennsylvania. Fourth edition. London: H. K. Lewis. 1897.—Less than two years ago we had occasion to pass a favourable criticism on the third edition of this work. The appearance of a fourth edition at so short an interval is evidence that it continues to find acceptance at the hands of the public for whom it is written. In its new form the book is enlarged, improved, and revised throughout. Professor Abbott has shown wisdom in the course which he has adopted, for it may safely be asserted that in the present state of knowledge any text-book on bacteriology must be out of date in two years and constant revision is necessary if it is to maintain its place as a text-book. We find no reason for any modification of the opinions which we have previously expressed as to the value of the work. Many of the illustrations are new and good descriptions of the micro-organisms of bubonic plague, influenza, and gonorrhœa have been incorporated in the text. The more important recent additions to our knowledge about the bacilli of typhoid fever and diphtheria receive due consideration. We can again commend the book to anyone beginning the practical study of bacteriology as a sound and useful manual which suggests even more than it directly teaches.

Il Piede e la sua Razionale Calzatura. (*The Foot and the Proper Form of Shoe.*) By Dr. F. BRUNELLI. Milan: Pietro Agnelli. 1898. Pp. 23.—In this pamphlet, which is reprinted from the *Giornale della Reale Società Italiana d'Igiene*, and is perhaps the most recent addition to the literature of the subject, Dr. Brunelli points out the defects of the ordinary shapes of shoe and explains how they are accountable for flat-foot, corns, bunions, ingrowing toenails, neuralgic pains in the feet and legs, varix, &c. In the normally shaped foot, such as that of a child six or eight years old, the great toe seems to turn slightly inwards, and the axis of its phalangeal and metacarpal bones when prolonged backwards passes through the centre of the heel. On the other hand, everybody knows that in the average adult foot the great toe is directed outwards, an unnatural position due to the use of ill-fitting shoes, and Dr. Brunelli proposes to avoid this deformity by giving the soles of shoes such a shape that when they are placed side by side the heels and all of the part from the ball of the toe to the extreme front of the shoe may be in contact without any approach to divergence of the inner margins from one another. He also discusses the shape of the front and outer edge of the sole, the width, square and broad toes, length, flexibility of materials, heels, the disadvantages of turning out the toes, &c. Although it will probably be long before his various recommendations become fashionable, Dr. Brunelli's book contains many useful suggestions which deserve to be known to medical men, parents, and others having the care of children, for distortions of the feet are more easy to prevent than to cure.

JOURNALS AND REVIEWS.

Archives de Physiologie. Publiées par MM. BOUCHARD, CHAUVEAU, et MARCY. 5me Série, Tome x., No. 2, 1898. Paris: Masson et Cie.—The articles contained in this part are the following: 1. MM. A. Dastre et N. Floresco, Pigments Hépatiques chez les Vertébrés. These observers divide the hepatic pigments in all classes of vertebrates into aqueous and chloroformic pigments; the former is soluble in water, contains iron, and has a continuous spectrum; the latter is soluble in chloroform, alcohol, and ether, but is insoluble in water and contains no iron. 2. Ergometric Studies, an Account of Some Conditions of Muscular Work in Man, by MM. André Broca and Charles Richet. Their experiments show first that the maximum of circulatory activity in the muscles takes place when repose succeeds to work (vaso-dilatation of Chauveau), and secondly that contraction is proportionately more vigorous and less painful as the circulation is more active. 3. M. Nikita Chodschajew, Enzymes: Are they Dialysable? He thinks they do dialyse but with extreme slowness. 4. M. J. Lefèvre: On the Evolution of the Thermic Topography of Homoiothermal Animals. Part 4: The Laws of Cooling. 5. Dr. J. L. Hoorweg of Utrecht: On the Physiological Action of the Closure of a Galvanic Current. 6. M. J. P. Morat: On the Transforming Power of Nerve Cells in Regard to Stimuli. 7. MM. A. Dastre and N. Floresco: On the Hepatic Pigments of Invertebrata. In the higher molluscous forms the pigments seem to be similar to those of vertebrates. The lamellibranchs possess the aqueous and ferruginous pigment or ferrine and whilst the anodonts have a chloroformic pigment resembling that of vertebrates named cholechrome with continuous spectrum the great majority, such as the oyster, muscle, and pecten, have the pigment named hepatochlorophyll, with four bands in the spectrum. In crustacea the pigments resemble those of vertebrates. 8. M. P. Yvon: On the Elimination of Sulphur and Magnesia. 9. On the Limits of Absorption of Carbon Monoxide by the Blood, by M. N. Gréhant. 10. On Duodenal Digestion of Albumin, by MM. J. Gachet and V. Pachon. These observers find with Schiff that in the living and fasting dog the pancreatic juice is not able to digest albumin experimentally introduced into the duodenum, but after ligature of the pancreatic ducts albumin introduced into a loop of the duodenum ligatured above and below is in large part capable of being digested. 11. On the Re-absorption and Elimination of Bilirubin, by MM. E. Wertheimer and L. Lepage. 12. The Muscular Work and the Rhythm of the Heart, First Memoir, by MM. J. Athanasiu and J. Carvalho. 13. On the Internal Secretion of the Spleen, by MM. J. Gachet and V. Pachon. The Researches of these authors show that the spleen produces a kind of ferment which in traversing the pancreas converts protrypsin into trypsin. 14. The Action of Suprarenal Extract on the Heart of the Rabbit, by M. E. Bardier. 15. On a Partial Decomposition of Chloroform in the Organism, by MM. A. Desgrez and M. M. Nigloux. 16. Contribution to the Study of the Chemical Actions of Pathogenic Microbes, by MM. L. Hugounenq and M. Doyon. 17. Experimental Researches on Diphtheria Toxin, by MM. Enriquez and Hallion. 18. Contribution to the Study of Osseous Regeneration on the Internal Prothetic Apparatus, by MM. M. Doyon and Cl. Martin.

Analytical Records
FROM
THE LANCET LABORATORY.

VEJOS AND FLUID VEJOS.

(VEJOS LIMITED, 143, WEST HAM-LANE, WEST HAM, E.)

"VEJOS" is described as a new vegetable extract obtained by extracting the protoplasm and proteids of certain vegetable cells with a weak solution of lactic acid at a moderate temperature. It is said that this treatment results in the gradual solution of the nitrogenous constituent of the cell, so that the albumin combining with the lactic acid forms an albuminate. At the same time other substances are extracted resembling the crystalline nitrogenous extractives of muscle. Salts, of course, such as the phosphates, would also enter into the solution. Before considering further the merits of the preparation as a nutrient we may give at once the results of our own analysis of this compound. They are as follows: Insoluble organic matter (cellular fibre), 3·45 per cent.; alcohol coagulum (albumins), 1·76 per cent.; alcohol precipitate (peptones, &c.), 17·59 per cent.; soluble nitrogenous substances, 21·02 per cent.; carbo-hydrates, 17·09 per cent.; soluble mineral matter, 11·30 per cent.; insoluble mineral matter, 2·77 per cent.; moisture, 25·02 per cent. The total soluble matter in the moist extract amounts to about 69 per cent. To the taste "Vejos" is barely distinguishable from good meat extract and, as the foregoing analysis shows, it presents practically the same chemical composition, with the additional advantage of a notable proportion of easily-digested carbo-hydrates. There can be little doubt, therefore, that "Vejos" is physiologically as valuable as a good meat essence. The analysis indicates it to be a powerful nutrient because of the excellent relative proportions of nitrogenous, carbonaceous, and mineral matters, and the condition in which these exist should favour their assimilation. "Fluid Vejos" is said to have for its basis the "Vejos" extract with the addition of 15 per cent. of a cereal treated in the same way as "Vejos" itself. According to our analysis it presents *chemically* very little difference in composition. The results were as follows: Alcohol coagulum (albumins), 1·20 per cent.,

alcohol precipitate (peptones, &c.), 20·44 per cent.; soluble nitrogenous substances, 18·42 per cent.; carbohydrates, 18·15 per cent.; soluble mineral matter, 13·68 per cent.; insoluble mineral matter, 1·92 per cent.; moisture, 26·19 per cent. The proportion of total soluble matter is somewhat less than in the previous preparation. Both preparations are free from objectionable preservatives.

AERATED WATERS.

(THE DORSET SODA-WATER COMPANY, LOWER BOND-STREET, WEYMOUTH.)

A point of first importance in the preparation of aerated waters is, of course, the employment of water of irreproachable quality. In this respect the preparations submitted to us by the above manufacturers were satisfactory. In the mineral waters we found no evidence of organic impurity. Further, they are prepared on the lines laid down in the Pharmacopœia. Thus the lithia water was found to contain 9 grains of the carbonate per pint; potash water 36 grains of the bicarbonate per pint; the soda-water 16 grains per pint of the bicarbonate (in this instance half B.P. strength). The alkalinity of the seltzer water was equal to 4 grains per pint of bicarbonate of soda, and the common salt amounted to a little over 6 grains per pint. With these preparations were submitted to us also specimens of lemonade, ginger ale, and an effervescing beverage termed "ozonine." All were pleasantly sparkling and quite bright. These beverages are evidently prepared with care.

VOLINE.

(S. WHOHLE, 237, SHAFTESBURY-AVENUE.)

Voline is described as an extract of certain tropical herbs which, when added in definite proportion to crude whisky, effects the precipitation of the injurious "substances" therein. We have tried several experiments in the direction indicated, but we are quite unable to confirm the statement that this vegetable extract has any other influence than that of imparting a foreign flavour to the spirit.

HEALTH FOODS.

(THE SANITAS FOOD CO., BATTLE CREEK, MICHIGAN. AGENCY: THE LONDON FOOD CO., 451, HOLLOWAY-ROAD, N.)

There are some novel and interesting dietetic preparations in the list of this company. They consist chiefly of foods prepared from cereals and from nuts. "Granose flakes," for example, consist of light brown flakes resembling potato chips, which on analysis present the composition of wheaten flour of superior quality—that is, flour in which all the essential food constituents are retained. The nitrogen amounted to 2·14 per cent., which is equivalent to a total of 13·37 per cent. albuminoids. The moisture amounted to 12·02 per cent. and the mineral matter to 2·09 per cent. The microscope showed the presence of starch granules highly distorted by cooking, probably by steam. The preparation is undoubtedly nutritious, not merely on account of its composition, but also because the constituents are partially prepared for the digestive process. "Nuttose" is an oily looking compound prepared from nuts. The fat is in a finely divided state amounting to an emulsified condition, while the carbohydrates and nitrogenous matters are previously treated so as also to render them easy of digestion. "Bromose" exhibits a composition balanced in accordance with physiological requirements. It is prepared in the form of tablets resembling caramels. It possesses a pleasant nutty taste, and here, again, the constituents are in a state favourable for assimilation. Lastly, the preparations submitted to us included "Caramel Cereal," which is offered as a substitute for tea or coffee. It consists of carefully roasted wheat and resembles coffee in colour and appearance and in the size of the grain. It yields on steeping in boiling water a rich infusion with aromatic coffee-like taste, which contains the nutritious constituents of the wheat berry. The preparations are of interest as indicating the steps which are taken to produce on a commercial scale foods in which the nutritive value is increased by the processes adopted.

"PERFECTED" COD-LIVER OIL.

(ALLEN AND HANBURYS, PLOUGH-COURT, LOMBARD-STREET, E.C.)

According to our examination this preparation justly merits its title. It is quite free from nauseous flavour and smell and is evidently well tolerated, since no objectionable eructations occur after its ingestion. The oil is remarkably bright and clear and has a slightly acid reaction. It possesses as far as possible all the qualities which render cod-liver oil not disagreeable to take. This is the result of paying great attention and care to the process of refinement and preparation.

BENSOLYPTUS.

(SCHIEFFELIN AND CO., NEW YORK. LONDON: POTTER AND SACKER, 7, FOWKES-BUILDING, GREAT TOWER-STREET, E.C.)

Bensolyptus is an agreeable and effective combination of pleasant antiseptics. It is a clear, colourless liquid possessing the delicate aromatic smell of gaultheria. It is alkaline to test-paper. On adding hydrochloric acid and cooling, a crystalline precipitate separates consisting of benzoic and boric acids. It can be employed as an agreeable mouth wash, and also administered to check fermentation in the stomach and intestinal canal. It should be useful also in the treatment of catarrhal inflammations of the mucous membranes. In fine it may be considered to be a mild yet efficient and non-irritating antiseptic.

SPECIAL BLEND OLD SCOTCH WHISKY.

(ROBERT CAIN AND SONS, LIMITED., MERSEY BREWERY, LIVERPOOL.)

Judicious blending is largely responsible for the satisfactory character of whisky, and in addition, of course, the spirit should be matured. Some evidence, as in the present instance, of both steps being taken may be gained from the results of analysis, but a discriminating taste is probably the best guide. The analysis of the above whisky was as follows: Alcohol, by weight 40·05 per cent., by volume 47·40 per cent., equal to proof spirit 83·07 per cent.; extractives, 0·28 per cent.; mineral matter, 0·01 per cent.; acidity equal to acetic acid, 0·036 per cent. The whisky is free from excessive colouring matters and extractives. The taste was quite in accordance with the statement that the spirit had been matured, and it is therefore of a wholesome character.

New Inventions.

A NEW CLINICAL THERMOMETER.

WE have received from Messrs. Maw, Son, and Thompson a clinical thermometer which by a simple device permits of the rapid readjustment of the index after an observation is taken. A comparative trial with a thermometer of the ordinary pattern soon establishes the superiority of the new instrument in this respect, for whereas to procure the return of the index to the normal after the mercury has been raised only a few degrees requires in the case of the former many and repeated vigorous shakes of the thermometer, with the latter one slight shake, or at the most two, accomplishes the end desired. Nor does such facile return of the index in the least affect the accuracy of the instrument as a recorder of temperature—indeed, our personal observation shows that it is not only reliable in this respect, but delicate and rapid in record. The improvement consists simply in the formation of a sort of reservoir for the index by means of an expansion of the tube above the bulb. As many a thermometer has been sacrificed in ill-directed efforts to shake down the index, this new invention may prove to be as economical as it will doubtless be a saving of both time and temper.

THE LANCET.

LONDON: SATURDAY, APRIL 16, 1898.

Is it possible to hope that the General Medical Council has held its last discussion on the principles which should regulate the grave step of giving to midwives a legal status? Either at the instigation of the Government of the day or on its own initiative it has for the last twenty-five years spent a great deal of its time and of the money of the medical profession in such discussions. For a quarter of a century this question has been debated in one form or another by the Council till at last that body has with practical unanimity formulated a set of fundamental principles which, if accepted, should keep the council-chamber clear of this thorny subject for the future, save, perhaps, when it may be asked to say categorically whether a given Bill sufficiently embodies the principles on which alone such a measure could be enacted in the interest of the public health, which is the chief interest.

Close observers of what took place in the General Medical Council last week must have been very much struck with the course of procedure. Ostensibly the discussion was concerned with the report and recommendations of the committee on the Midwives Registration Bill, which laid down certain principles which our readers may study for themselves in the columns of THE LANCET. The chief of these principles were as follows:—That midwives should henceforth be registered and subject to rules of practice to be drawn up by a Midwives' Board consisting of medical men elected in England by the three medical corporations and a chairman appointed by the Lord President of the Council; that all the rules of the midwives' board should be subject to the approval of the General Medical Council; the claim to admission to the register was to be on the ground of previous practice as a midwife, or of a certain amount of training and examination to be determined by the midwives' board; that midwives were to be restricted to attendance on natural labour and that on the occurrence of anything unnatural or unsatisfactory in the mother or child they were to apply for the assistance of a registered medical practitioner; that the local sanitary authority should be required to appoint as many practitioners in every locality for this purpose as should agree to be so appointed and pay them a proper fee; and that no woman should be allowed to practise as a midwife, habitually and for gain, unless she were registered, such registration to be annual and for a nominal sum. An excellent clause providing that no woman or any association of persons founded for the purpose should, either habitually or for gain, attend or undertake to attend on a lying-in woman, unless the person attending and all the members of any association providing such attendance were registered according to the provisions of the Act was included in the recommendations of the committee as well as one to prohibit the employment of unregistered substitutes by registered midwives. A clause prohibiting the granting of certificates of stillbirth and other medical certificates was very properly one of the recommendations of the committee. The committee recommended the insertion of a clause forbidding the granting of certificates in midwifery by any person or body not legally authorised to grant them. It was also provided that as the time of the Council would be occupied, at first considerably, by its duties under any such Act it should be reimbursed for any expenditure on this account.

Such were the principal recommendations of the committee which the Council on Tuesday, April 5th, resolved to discuss *seriatim*. On the following day, after the passing of a resolution expressing sympathy with the family of the late President in their and the Council's loss and the acceptance of a slight amendment to the recommendation of the committee as to the definition of a midwife, Dr. MACALISTER asked that he should be allowed to make a statement and certain motions in substitution of the general considerations and recommendations of the committee and that those resolutions should constitute the reply to the Lord President. These resolutions were practically those of the committee, as he candidly admitted. There was, however, one important exception which constituted a veritable amendment. Basing the suggestion on a remark in a speech made by Sir WILLIAM GAIRDNER on the previous day he proposed that midwives instead of being *registered* should be *licensed* and that the licence should be issued by the local sanitary authority, should be renewable yearly, and should be revocable at any time in case it should be proved that the holder had infringed any of the prescribed regulations. This suggestion was immediately accepted both by the President and the Council together with the motions attached to it. As far as these latter went, as we have said, they were practically those of the committee. It was amazing to see the rapidity with which the substitution of licence for registration seemed to dissipate all other opposition and the motions in substitution of those proposed by the committee were quickly accepted even by members of the Council who had previously refused to entertain the similar proposals of the committee. Whatever the members of the committee may have felt in regard to the turn of the discussion they did not allow their feelings to affect their votes, and the reply, as formulated by Dr. MACALISTER, was adopted unanimously by the Council. Unfortunately one or two of the recommendations of the committee were left out in the cold, particularly the one requiring the local sanitary authority to appoint (and, of course, pay) medical practitioners to whom the midwives might apply. Mr. CARTER could see in this reasonable proposal nothing so much as a little trades' unionism which would excite offence in Parliament. Another rejected suggestion of the committee was the one intended to prevent illegal practice by association. It is certainly, we think, to be regretted that the Council dealt so vaguely with the vital question of the midwives' board as "some central body" without any suggestion as to its constitution, on which everything turns; and it seems a pity that in disregarding the lead of it committee the Council failed to express

itself on the subject of medical certificates and certificates of stillbirths.

It would seem therefore that some of these changes are not for the better and may cause much more trouble and loss of time on future occasions. But the discussion of 1898 should as far as it goes be considered final. It accepts the fact that there must for the present be midwives; it proposes to stop the deadly practice of untrained midwives by prohibiting practice as well as the false use of titles; it recognises the necessity for the practical supervision of midwives by the medical profession and the authoritative regulation and restriction of midwives' practice. It is impossible for the General Medical Council to approve of legislation on this subject except on such lines. The substitution of a licence for registration may not have the same magical effect on the profession that it had on the Council; but it does tend, and very properly tend, to minimise the recognition of a class of persons who ought in the evolution of society to disappear. The Council has defined its position and the Privy Council cannot be at any loss in the future to know the attitude of the General Medical Council towards this legislation. Under the circumstances we may confidently hope that Parliament, if the Bill should come to a second reading, will see its way to oppose it in its present form. If its promoters wish to stop puerperal mortality at the hands of midwives they, too, will accept the principles unanimously laid down by the General Medical Council or abandon attempts at legislation which would practically leave things where they are.

THE question regarding the Vaccination Bill raised by Mr. HUTCHINSON in a recent letter to us[1] is one which demands serious consideration. He recalls the fact that the Royal Commission on Vaccination advised that State payment for successful vaccination should no longer be made exclusively to those holding appointments, but that under certain conditions all medical men should have a right to claim such fees, and he points out that the Bill gives no effect to this advice.

It is well known that the Commission laid great stress on the comparative absence of friction or difficulty attending the administration of the Scottish Vaccination Act. The recently published report of the Registrar-General of Scotland for the year 1896 shows less than 3 per cent. of vaccination default, while in England in 1894 the cases not accounted for had risen to 19 per cent., and the percentage is now, no doubt, even higher. Clearly it is most desirable that whatever is good in the Scotch system should be adopted south of the Tweed. The Commission's recommendation of domiciliary vaccination is based on the fact that in Scotland, excepting in two or three of the largest cities, public vaccination stations are practically unknown. Mr. CHAPLIN has followed the Commission to a certain length here and then he has abruptly stopped. Nearly all vaccinations in Scotland are performed by the family medical attendant, and the absence of friction which distinguishes the whole procedure is probably in great measure due to that custom. Some time ago[2] we published a series of articles dealing with the relations of the medical officer of health to the private practitioner and we then took occasion to point out how judicious it is for the public official, especially when engaged in private practice, to avoid needless domiciliary visitation in houses where patients of his brethren in practice are suffering from infectious disease. With regard to vaccination the necessity would probably be even greater, for here there would be not merely an inspection of the house but the performance of a small operation on one of the inmates. The Bill takes no cognisance of this difficulty. It proposes domiciliary vaccination, but leaves out the private practitioner. The Scotch system, however, has defects of its own. The private medical attendant is not under that system paid by the State, his work is not supervised by the State, and he does as he pleases with regard to the amount of vaccination of every individual case. Whatever be the case in Scotland, where opposition to vaccination is much less keen, in England such a system would almost certainly result in some lowering of the efficiency of vaccination in consequence of frequent parental pressure towards diminution of the area or number of vesicles. We therefore appear to have arrived at this position, that if the advantages of the Scotch system are to be obtained for England the private practitioner should be very generally employed where domiciliary vaccination is in question, but that if its disadvantages are to be avoided his work should be State-paid and State-inspected. If the Local Government Board decides that a particular area and number of vesicles are necessary for reasonable efficiency and duration of protection, then it should have the right to refuse payment for any case which does not fulfil the required conditions. Here, however, an important practical difficulty arises. The work of perhaps 4000 public vaccinators may in some degree be supervised by the Board's inspectors, but if every medical man may claim fees how is his work to be supervised? At present the public vaccinator has usually a large number of cases in his books and sampling is comparatively easy, but if a practitioner performs only a dozen or two vaccinations in a year, and if in a given community there are to be, say, fifty practitioners sending in returns instead of one or two, the problem of inspection becomes at once a very difficult one. It seems to us that if the central authority cannot add sufficiently to its staff, then in many places the medical officer of health might be made the inspector of vaccinations—at least where he is not engaged in general practice. He is already in relation with the Local Government Board and the points of contact would only be increased, while he himself would be under supervision by the Board and its inspectors in this department of his work. It is not to be assumed that an undue amount of his time would be taken up in this way. Going about continually in his district he could do a great deal of casual inspection which would require special visits on the part of an officer having no other work in hand.

It may well be argued that if as a result of domiciliary vaccination any large transference of work were made from public vaccinators to private practitioners some slight loss of efficiency might follow and that, other things being equal, skill and dexterity go hand-in-hand with experience and that this holds good even in so simple an operation as

[1] THE LANCET, March 19th, 1898, p. 813.
[2] THE LANCET, Jan. 19th and 26th and Feb. 9th and 16th, 1895.

vaccination. Looking to the very high "insertion success" attained by some public vaccinators, it is probable that, taking a large average of cases, a private practitioner aiming to produce four vesicles will fall short of his endeavour somewhat more frequently than a public vaccinator. On the other hand, a large amount of the vaccination of the country is already done by non-official medical men, and here, under even a minimum of Government supervision, there would be an improvement in practice. A residuum of cases would still, no doubt, exist as to which no fee would be claimed or paid, the necessary standard of efficiency not having been reached, perhaps not even attempted or desired.

In what we have said here we do not for one moment suggest that there should in future be no difference between the position of the public vaccinator and that of the private practitioner. The work of the latter would be merely complementary or supplementary to that of the former. If we understand the purpose of the Government aright they do not intend to abolish vaccination stations but only to allow a choice on the part of parents. At the station the public vaccinator would have the sole control. Under Clause I. (2) of the Bill it would be only the public vaccinator whom the parent would have a right to call on for domiciliary vaccination, and under the succeeding sub-clause it would be the public vaccinator who would be supplied with lists of children reaching the age of nine months without having been vaccinated and whose homes it would be his duty to visit in order to offer vaccination with glycerinated calf lymph. For all such work he must, of course, be properly remunerated. If some scheme such as is sketched here were brought into operation it is not unlikely that the work of infantile vaccination would be largely accomplished within the first nine months of life, and that a not inconsiderable part of it would be done by private practitioners, either at the child's home or at the medical attendant's consulting-room. But this, we take it, is exactly what the Government and the Commission and the public desire. The whole question must be looked at primarily from the point of view of the public weal, and we see much force in Mr. HUTCHINSON'S contention that the total numbers of the vaccinated would in this way be increased and the reluctance of mothers to submit their children to vaccination be greatly diminished. One thing, however, should be kept clearly in view. No such system of infantile vaccination would obviate the necessity for the Government dealing with the question of revaccination. Systematic vaccination at twelve years of age is essential under whatever scheme the earlier protection may have been obtained. And the very fact that some diminution of "insertion success" may take place in primary vaccination forms another argument in favour of revaccination being regularly carried out as a duty of the State to the individual and to the community.

THE Ninth International Congress of Hygiene and Demography was opened at Madrid on Sunday, April 10th, in an extraordinary environment. Madrid is at the present moment the centre of the highest political and patriotic excitement, for whether or not the outcome of President MCKINLEY'S voluminous message be the declaration of war the prestige of Spain is seriously assailed by the fact that the United States should have thought well to level at her so direct a threat. The national characteristic of the Spaniard being the reverse of humility it is unlikely that Spain will accept dictation without remonstrance, so that whatever the eventual issue Madrid will be for some time, as it is now, a troublous place for the holding of a scientific Congress. Our Special Correspondent reports that the preliminary business of the Congress was transacted laudably under the circumstances and it is obvious that every attempt is being made by the sorely tried Government to welcome the international representatives of public health in a way befitting a great nation. For this gallantry under difficulties we are certain all our readers will share our sympathy.

It is sincerely to be hoped that the proceedings at the ninth Congress will be definite in their object and perhaps a little more limited in their scope than they have hitherto been. Such subjects as hygiene and demography are so all-engrossing that it is easier to allow the debates to become diffuse than to keep them concentrated upon useful points. If certain fixed questions of prime importance were to be made the subject of set discussion by accredited representatives, and if such debates had their outcome in resolutions which could afterwards be submitted to full Congress for voting, the cause of international sanitation would be really advanced. Hitherto the work done at these congresses has been too scattered in its aim to be of the first benefit to the world. The very large scope is not without advantages but the advantages were more solid in earlier days. When the congresses were first instituted it was necessary that the various nations who attended them should compare notes all along the line before attempting to draw conclusions. The plumbing of one nation, the bacteriology of another, the sewage disposal of a third—all required to be brought to the general knowledge of the delegates before it could be determined what was common property and what were the universal desiderata. But the earlier congresses have more or less settled these things and for the future leisure should certainly be found at these meetings to thoroughly discuss, by the mouthpiece of accredited delegates, a few questions of undoubtedly prime importance—subjects upon which all civilised nations desire enlightenment. The unanimous advice of a meeting of experts from all parts of the world might sway Cabinets in their international relations; a brilliant paper read to one section of an international congress—possibly in a language not familiar to the majority of the audience—runs a risk of falling stillborn from its author's lips.

In THE LANCET we have specially recognised the utility of congresses as a means of spreading a knowledge of sanitary laws, even when we have seen that this utility might be increased, and we have in particular from the very first appreciated the work of the International Congresses of Hygiene and Demography. The first of these was held at Brussels in September, 1876, and then, at a time when the importance of the movement was hardly recognised by all, we dispatched a

special correspondent with a mission to describe in these columns the scientific proceedings at the meeting and the exhibition of hygienic appliances. At all the subsequent congresses save one we have been represented by a correspondent who has frequently taken an active part in the debates and who has been on several occasions selected as the spokesman of the entire English delegation, while he has always been responsible for sending to us the longest and fullest descriptions published by any English journal. We have, in short, taken every pains to display our belief in the value of these congresses. We mention these things in spite of their egotistic appearance because it seems to us that some of the sanitarians of this country do not regard the International Congresses of Hygiene and Demography with sufficient seriousness. For how else are we to explain the absence from Madrid without notice of three English members of the Permanent Committee? These gentlemen must have thought that their abstention, with the loss to English organisation so entailed, was of no consequence. We think otherwise, and much regret that our country has been placed under a cloud on the very occasion of all others when we have a right to expect to shine—namely, at an international assembly concerning itself with public health.

Annotations.

"Ne quid nimis."

THE SMALL-POX EPIDEMIC AT MIDDLESBROUGH.

ALTHOUGH unhappily cases of small-pox continue to be notified at Middlesbrough at the rate of from 30 to 40 per week, this is so marked a diminution on the returns of a few weeks back that the epidemic may be said to be declining and it will, we hope, shortly be at an end. There has been issued by the Jenner Society an instructive pamphlet upon the outbreak prepared by Dr. F. T. Bond of Gloucester. In this he points out that the epidemic commenced towards the end of November and was of such magnitude that from Nov. 22nd, 1897, to March 21st, 1898, there had been 1200 cases with 153 deaths. Within the same period in 1895–1896 there were at Gloucester about 850 cases with 212 deaths. Observing that it is, of course, impossible to say what the precise fatality of the Middlesbrough epidemic will be, Dr. Bond, in order to carry out the comparison with the Gloucester outbreak as fairly as possible, deals statistically only with those cases which were notified up to the end of February—namely, 686—of which 97 were fatal, or 14·1 per cent. With the same number of cases (686) at the same stage of the Gloucester epidemic there were 172 deaths, a fatality of 25·0 per cent. He then proceeds to analyse this difference in fatality by reference to the condition as to vaccination of those attacked. At Middlesbrough 581, or 84·7 per cent., had been vaccinated in infancy; at Gloucester 368, or 55·5 per cent. But the fatality in this class was almost the same in the two places, the "vaccinated" deaths being 48 in Middlesbrough, or 8·2 per cent., and 32 at Gloucester, or 8·7 per cent. Similarly, of the 105 "unvaccinated" at Middlesbrough 49 died, or 46·6 per cent.; and of the 318 "unvaccinated" at Gloucester 140 died, or 44 per cent. Clearly, then, the excess of deaths in the Gloucester outbreak as contrasted with that of Middlesbrough was due to the greater number of unvaccinated subjects attacked by small-pox. The contrast is pushed still further by analysing each of these series in respect to age-incidence. In Middlesbrough 95 per cent. of the vaccinated who were attacked were over ten years of age (nearly 70 per cent. between twenty and sixty years), whilst less than 5 per cent. were under ten years. In Gloucester more than 98 per cent. of the "vaccinated" attacks were in subjects over ten years of age (73 per cent. between twenty and sixty years) and less than 2 per cent. were under ten years. As regards the unvaccinated, 90 per cent. of the attacks at Gloucester were in subjects under ten years of age; in Middlesbrough less than one-third of the unvaccinated were under ten years, but only 2·8 per cent. were between twenty and sixty years of age. The Middlesbrough epidemic is therefore analogous to that at Warrington in 1892–93, having been "mainly one of small-pox occurring in adolescents and adults who have been vaccinated in infancy, and have so far lost the full benefit of the protection they then received. But they were still sufficiently protected to make the mean fatality of the whole group only 8·2, which is mainly due to the high fatality amongst those who were attacked between twenty and sixty years of age." Dr. Bond points out that Middlesbrough has been wrongly styled a "well-vaccinated town," for although the latest vaccination returns (of 1896–97) showed a default of infantile vaccination of only 7·2 per cent., yet the census instituted by the board of guardians in February revealed out of an enumerated population of 69,525 as many as 653 unvaccinated children between the ages of three months and fourteen years, and therefore probably at the commencement of the epidemic as many as 1000 to 2000. Nor is there any evidence that as regards revaccination its adolescent and adult population were any whit better off than any other town. In truth this outbreak comes as it were to demonstrate once more the fact that small-pox is not to be warded off by infantile vaccination alone and that revaccination is just as much called for if the disease is to be kept in check once the infection has gained a footing. What has happened to Middlesbrough may happen to any town in the kingdom, provided that facilities for personal infection exist in like abundance; and if reliance were to be placed on isolation and "sanitary police measures" alone the cost to the community would be enormous, since no place is prepared to deal with small-pox without the aid of vaccination and revaccination.

THE VICTORY IN THE SOUDAN.

THE present Government has unquestionably had during its term of office its full share of trials, political perplexities, and anxious problems on all sides. The state of India, with its famine, plague and pestilence, and the war on the frontier, which was attributable to the fact not that we would not leave the tribes alone but that they would not leave us alone; the paralysis of China and the dismemberment of that vast Eastern Empire by the Western Powers, together with entanglements, wars and rumours of wars in Eastern, Western, and Northern Africa,—these have given the India and Foreign Offices but little rest of late. If our political difficulties and embarrassments have come together so have our successes. The promised termination of the war with the border tribes on our North-west Indian frontier, the successful result of our diplomacy in China and the far East, and the news of the great and brilliant victory in the Soudan, by which the Mahdist power in North Africa has been broken and a large portion of the Khalifa's army practically annihilated, have followed one another with dramatic rapidity to the great relief of the present Government. The campaign in the Soudan has been designed with great strategical, and carried out with equally great tactical, ability and success. The military situation in the

Soudan immediately prior to the successful attack of the Anglo-Egyptian force on Mahmud's entrenched position was one of unusual interest, because Mahmud could neither advance nor retreat without the gravest consequences to his force. The battle of Atbara has been attended with an estimated loss of some 3000, and all the important Emirs, except Osman Digna, have been slain or taken prisoners, including among the latter Mahmud himself. The loss on the Anglo-Egyptian side amounts to upwards of 500 killed and wounded. The medical arrangements appear to have been extremely good, and as there was ample time before the attack on the Khalifa's force took place everything had been well thought out and provided. The work of stripping the battlefield of its wounded was a hard one, but it was performed as expeditiously as possible. The sick and wounded were first of all cared for at Ras Hudi. There is excellent hospital accommodation at Atbara Fort and on the banks of the Nile, and the last convoys of sick and wounded arrived at Atbara on April 11th after a trying journey which was admirably conducted and borne. They will be transported thence by the best and easiest of all transport for wounded men—namely, along the Nile in large boats with sunproof coverings—to the base hospital at Gennanetti. The sick and wounded have received every comfort and attention which medical care and skill could devise and it is allowed on all hands that the arrangements for affording surgical succour and aid on the field and those for the hospital service generally were most satisfactory. The wounded, according to the latest accounts, are all doing as well as could be expected. We have only to add our congratulations to those which Sir Herbert Kitchener has already received for himself and the brave force under his command, supplemented by the congratulations which we have to offer to the medical officers of the British and Egyptian services for the hard and successful work which they have accomplished.

THE RIGHT TO PRACTISE IN NATAL.

THE *Transvaal Critic* of Feb. 11th is much exercised about what it calls a medical ring. After some cheap sneers about "butchers" and "doctors paying the funeral expenses of their 'clients,'" the writer proceeds to take to task the Medical Council of Natal, a body constituted by Act 35 of 1896, which Act gave the Medical Council the right to frame certain regulations for the practice of medicine and surgery in Natal. According to this Act, "no person shall be permitted to practise or be registered as a medical practitioner unless he would be entitled to be registered in Great Britain or shall have obtained a licence from the Colonial Secretary on the recommendation of the Council." The Act goes on to say that to get such a licence the person desiring it shall provide proof of identity, authenticity of diploma, and of his right to practise elsewhere under such diploma. Now, according to the *Transvaal Critic*, the Medical Council have in their regulations on this Act altered the words "right of the holder to practise elsewhere under such diploma" into "submit a declaration that they are entitled to practise as qualified medical practitioners in Great Britain." Apart from the view that in all probability a "regulation" of the Medical Council cannot and does not override the Act of the Colonial Government, such a regulation would not in the least prevent "any fully qualified French or German doctor who may not have also practised in Great Britain from practising in Natal." The *Transvaal Critic* says it will. Any qualified—or, for the matter of that, unqualified—person may practise in this happy land of England. Any person, however, may not be *registered*. If the Medical Council of Natal wish to prevent any one who has not a British registrable qualification from practising in Natal let it say so and take steps to gain its wish. It is, of course, a natural enough, though we think a mistaken, view. The Act quoted is narrow enough to keep out the quack, it is far more stringent than anything we have over here, and the Natal Medical Council might well bear in mind the objections raised when it was proposed to make all English-speaking practitioners in Italy undergo the same examination as their Italian *confrères*.

SCHOOL BOARDS AND MEDICAL CERTIFICATES.

THE West Bromwich School Board met on April 5th, when the question of medical certificates came to the front. Mr. N. L. U. Somers, a medical practitioner, moved the following resolution: "That having regard to the fact that the parents or guardians of a child unable to attend school through illness comply with their legal obligations by furnishing a certificate to that effect signed by any duly qualified medical practitioner this Board considers such certificate as sufficient evidence of a child's inability to attend." Mr. Somers cited a case where a medical man certified a child as suffering from scholiosis (*sic*). This child was then sent to the medical officer of the Board, who had previously examined her and reported in favour of her attending school. He said that he did not examine the child a second time, that he presumed the disease really was "scoliosis" but that he would examine her again if they wished. The resolution was carried eventually by six votes to three, two members not voting. This is as it should be. Every qualified medical man is not immaculate any more than every cleric or every lawyer, but in any case he knows better whether a child is able to attend school than does a layman, and we suppose that a layman is the one who decides whether a certificate shall be revised by the Board's medical officer or not; erratic spelling is not necessarily a proof of professional incompetency. School boards are curious bodies and seem to mistrust everyone with whom they come in contact unless they receive payment from funds administered by the Board and extracted from the pockets of the ratepayers.

AN ALLEGED OUTBREAK OF OYSTER-BORNE ILLNESS.

IN a leading article in THE LANCET of April 9th we insisted upon the fact that oyster-borne enteric fever was by no means the only danger to be feared from the consumption of sewage-polluted oysters, and we drew attention to an outburst which occurred in France, in which out of 14 persons who consumed polluted oysters obtained from Cette, 12 suffered from gastric disturbances and 2 from enteric fever. Curiously enough Mr. Edward Sharp, the medical officer of health of Truro, relates in his annual report, which we have just received, an instance involving 7 persons who sat down to a supper at which uncooked oysters were partaken of. Out of these 7 persons, all of whom ate oysters, 4 suffered from gastric symptoms of more or less severity, 2 subsequently developed enteric fever, and the remaining one, who by the way ate oysters freely, escaped unhurt. The evidence against the oysters is, as Mr. Sharp observes, very strong, though there would apparently remain the objection which has probably been discounted, but which is not referred to in the report before us, that the 6 persons attacked ate or drank of something which was not partaken of by the person who remained well. However, oysters derived from the same laying as were those under suspicion were sent to Dr. Kanthack for bacteriological examination and we are told that "they showed fair evidence of sewage and filth contamination." The oysters here in question were derived from near Malpas, in the Truro River, and we see by reference to the Local Government Board report on Oyster Culture in Relation to Disease that in the opinion of the inspector who conducted this part of the inquiry "there is no escape from

the conclusion that oyster layings near Malpas and in the upper waters of the reach below it must be liable to contamination" and that "at Malpas there are slop-water sewers from about twenty houses, and also a privy, discharging themselves dangerously near one of the ponds and some of the small layings to which reference has already been made." We note, however, with satisfaction that the sanitary committee of the Truro Corporation has recommended that the laying down of oysters on the Malpas foreshore, even for temporary purposes, should be prohibited; but it is to be regretted that the prohibition was not made and carried into effect when the Local Government Board report was issued and hence before the drastic experiment here referred to had been performed.

THE TREATMENT OF TETANUS.

OUR Rome correspondent writes, under date April 3rd "From Palermo I hear that Dr. Francesco Supino, on the veterinary staff of the cavalry regiment quartered at Monferrato, having got none but negative results from the Tizzoni antitoxin in treating a horse for tetanus, had recourse to serotherapy. He took the serum from a horse that had been cured of tetanus and on the 14th ult., at 4 P.M., he made a first injection of 100 grammes of the serum, introducing it subcutaneously at the neck and suspending all other treatment of the suffering animal. Next morning at 8 he noted a marked general improvement—facility in movement, deeper respiration, pronounced diminution of the trismus, and the eye more expressive. Continuing the practice at intervals of twenty-four hours, he made four other injections of 100 grammes each and always had occasion to note improvement—improvement, indeed, so uniform and progressive as to admit of the horse's lying down and raising himself (a thing he could not do at first) without external aid. The animal (I hear to-day) is in full convalescence and is led out by hand for an airing "senza preoccupazione" (without antecedent trouble). Dr. Supino adds that serotherapy has had previous trials in tetanus, but not with the above indicated means, of which a detailed report may shortly be looked for from his pen."

MEDICAL LECTURES TO LAY AUDIENCES.

WE learn from the *Nottingham Daily Guardian* that a deputation introduced by Alderman Mutch, M.D.Aberd., consisting of the President and several influential members of the Nottingham Medico-Chirurgical Society, recently had an interview with the Watch Committee of Nottingham on the subject of lectures on medical subjects to lay audiences. The deputation, representing a society consisting of over one hundred members, stated that their object was to record their opinion that certain lectures on medical subjects such as had recently been delivered in the city in places of public resort to promiscuous audiences were most undesirable and calculated to do a great deal of harm. They gave a great many facts in support of this view and explained that their action was taken on purely public grounds and not out of selfish regard for professional interests. They did not consider that any injury was done to regular practitioners by the visits of itinerant lecturers, but thought these public lectures tended to excite morbid curiosity and to disturb the minds of susceptible persons. The Watch Committee, we are glad to learn, undertook to use such powers as they possessed to prevent a recurrence of the practices objected to by the deputation. The recent lecturers who have undertaken to enlighten the lay mind of Nottingham on medical subjects were Mrs. Longshore Potts and a certain "Professor" Wells. We notice that the Nottingham Medico Chirurgical Society rightly base their objections to the methods of these people on the highest moral grounds, but we should like, in addition, a little information upon the narrower professional side of the matter. Do not these persons under the guise of imparting useful knowledge of the laws of health really aim at getting money from those who listen to them? Otherwise how do they live and who pays their railway fares?

ICHTHYOSIS AND ARTERIAL ATROPHY.

MM. GASTOU and EMERY furnish an interesting contribution to the pathology of ichthyosis in the *Journal de Clinique et de Thérapeutique Infantiles* of March 24th, 1898. The disease as observed by them occurred in two children aged respectively twelve and ten years and was of the granular variety, each hair being the centre of a minute horny plate. Their father was troubled with the same condition of skin and he, two years before the birth of the elder child, had syphilis. The most interesting feature about these cases, however, is that they exhibited a conjunction of ichthyosis with marked arterial attenuation as expressed in a hardly perceptible thready pulse in both radial arteries with cyanosis of the extremities. This peculiarity has also been noted in ichthyosis by M. Variot. MM. Gastou and Emery regard both the skin disease and the arterial shrinking as evidences of a common dystrophic change—possibly in these cases related to the parental syphilis but not necessarily dependent on this cause as a rule. They note another case in which the same condition of skin and blood-vessels was observed by them and in which the underlying hereditary taint was that of tubercle and they believe that alcoholism and other hereditary disorders exercise the same influence.

THE VACCINATION BILL AND THE JENNER SOCIETY.

THE Jenner Society—or rather its indefatigable secretary, Dr. F. T. Bond—has issued sundry leaflets upon the Vaccination Bill which may be commended to the notice of our legislators. In one of these the measure is critically examined and regret is expressed that children may be exempted from vaccination entirely if the parent pays a pecuniary fine—supposing, that is, that the law is enforced at all; and there are places where it may be doubted whether it wil be set in action in the future any more readily than it has been in the past. It is contended that a far more logical course would have been to suspend the operation of the law when objection is taken not indefinitely but perhaps until school age, when vaccination might be made an essential to admission to school. It is not unlikely, too, that objections to vaccination would be less strong when the child is older. Many cogent reasons are adduced in the pamphlet for transferring the vaccination authority from boards of guardians to the sanitary authorities—i e., the district and town councils—and as far as possible to combine the offices of medical officer of health and public vaccinator. As regards other provisions in the Bill it is feared that the extension of the statutory age to twelve months may increase rather than diminish the risks of septic infection and that difficulties are likely to arise in domiciliary vaccination as well as dangers of septic injuries in vaccinations performed in unhealthy homes. It is also urged that the Local Government Board should be empowered to define "sufficient" vaccination, to inspect all vaccinations (public or private), and to keep a register where all particulars of the vaccination should be entered from detailed certificates. Amongst other suggestions is one recommending the enforcement of vaccination and revaccination during the existence of small-pox in a neighbourhood on all occupants of houses who, being under fourteen years of age, have not been sufficiently vaccinated or re-vaccinated. There is a good deal to be said for most of the proposals which Dr. Bond makes in this able *brochure*

and we would welcome them as changes that could be affected without much reconstitution of existing machinery. Another leaflet issued by the Jenner Society contains excerpts from articles in the press on the Vaccination Bill. They indicate that public opinion is by no means unanimous as to the advantages likely to accrue from the proposed alterations in the law, and in reading them it is impossible to avoid the feeling that, in spite of the labours of the Royal Commission and the abundance of facts which it accumulated, the public is still but imperfectly instructed upon the question. Whether the House of Commons is any better informed may perhaps be seen in the debate which will arise on the second reading of the Bill. No doubt the situation is one of singular difficulty, since there is every reason to believe that so long as vaccination is attempted to be enforced by penalties there will be "vaccination authorities" determined to abstain from the use of the powers entrusted to them. The suggested substitution of "suspension" for the infliction of penalties made by Dr. Bond might provide a way out from an "impasse" which is rendering the English administration of Vaccination Acts somewhat ridiculous.

THE DANGERS OF IMPORTED MILK.

PUBLIC attention is very properly being directed to the possibilities of foreign milk being not only infected but also injurious owing to the addition of certain preservatives. We have long urged that the sharpest possible outlook should be kept upon all articles of food coming into this country from abroad. Not long ago we alluded to a report drawn up at the instigation of the (late) Commissioners of Sewers in which there was quite sufficient evidence to show that the milk imported into this country from several countries on the Continent was distinctly open to suspicion, since no precautions appeared to be taken in the care and management of the cattle supplying the milk intended to be sent out of the country. The quantity of foreign milk imported into this country is rapidly increasing, as is evident from a report recently issued by the British Consul at Cherbourg. Thus from this place no less than 76,383 gallons were sent to this country during the three months ending on Dec. 31st last year. And this importation goes on without any guarantee that the milk is free from infection or that it is produced under healthy environment. Further, a new practice is reported to have arisen, which consists in the adding of a vegetable extract which is said to serve as a preservative of the milk for several days. This addition is reported to be beyond chemical detection and the added substance is lost on evaporation. The preserving power of the vegetable extract was suggested from the fact that when cows had partaken of the plant from which the extract is prepared it was observed that the milk yielded remained sweet for an unusual time. The matter, it seems to us, is one which should receive the earliest possible attention, as such an addition may not unlikely prove to be a source of very serious mischief to consumers.

AFFECTION OF THE HEART IN CANCRUM ORIS

IN the *Edinburgh Medical Journal* of March, 1898, Dr. Thomas Oliver has published the following case. A domestic servant, aged seventeen years, who had a comfortable home and had always been well fed, began to suffer from faceache, attributed to a decayed tooth. A day or two later an ulcer formed behind the left upper incisor teeth, which was followed by swelling of the cheek and ulceration of its inner surface. The pain continued and was accompanied by frequent shiverings and prostration. When the patient was first seen, three weeks after the onset, the left cheek was considerably swollen, red, and indurated and the left half of the upper lip was swollen and protruding. There was a large brawny swelling below the chin and the breath was very offensive. The teeth were loose and the gums were red and ulcerated. There was a large ulcer on the floor of the mouth and another on the inside of the cheek, each covered with a slough. The heart was normal and the temperature was 102° F. Three days later friction sounds were detected over the right base and bronchial râles all over the lungs. On the following day the patient was very ill, the bronchitis was worse, and the pulse was 140 and rather irregular. The area of cardiac dulness had increased, the impulse was flapping and more diffused, the apex beat was felt in the fourth space ½ in. external to the left nipple. The area of dulness rapidly extended, the apex beating 1½ in. external to the nipple and over this area was a loud-blowing systolic murmur. At the end of the fourth week the cheek became perforated. By degrees the health improved and the heart became reduced in size, but the murmur could still be heard several months after recovery. The remarkable points in the case are the occurrence of the disease in a subject who had not passed through a previous illness or been exposed to any unfavourable influence, the age of the patient, and the heart complication. Dr. Oliver attributes the dilatation of the heart to malnutrition of the myocardium either from fever or toxæmia; a similar condition occurs not uncommonly in fevers. He thinks that the murmur was due to the dilatation and not to endocarditis. This view appears to us to be scarcely satisfactory. The persistence of the murmur after the dilatation had passed away is opposed to it. Moreover, cancrum oris, like other suppurative foci, would at least give an opportunity for pyogenic or other infection of the endocardium, and so long ago as 1878 Dr. A. E. Sansom described in the Transactions of the Royal Medical and Chirurgical Society an organism found in the blood and diseased tissues.

"PROFESSOR D'ODIARDI" AND HIS ELECTRICAL HOSPITAL.

MR. DREW, the coroner for West London, held an inquest at the Kensington Town Hall on April 12th concerning the death of a man, aged seventy-eight years, who was found dead in a house in Peel-street, Campden-hill, on Good Friday. The landlady of the deceased deposed that he had attended the Notting Hill-gate Free Hospital at 30, Silver-street, and had had the battery applied. Annie Bridge, a nurse, said she was engaged at the "Electrical Hospital," but had had no previous training. There was a staff of six nurses, and Dr. Walton of Swanage, the consulting physician, never saw patients. "Professor" D'Odiardi did. As, however, we are unable to find any medical man of the name of Walton in practice at Swanage in either the current Medical Register or the Medical Directory, perhaps this does not much matter. Mr. D'Odiardi in his evidence said that he had had no medical training nor had he any qualification. He had worked under well-known doctors, and his advice and instruments had been accepted by the Dean of the Medical Faculty at Belgium. He had founded the hospital and received no salary. Deceased had paid £3, but upon his saying he could not afford more he was treated for nothing afterwards. He was of opinion that deceased had catarrh of the stomach. Mr. A. K. Barrett of Peel-place said the post-mortem examination revealed old valvular disease and pericarditis with Bright's disease. There was no catarrh of the stomach. The coroner said that the "professor was absolutely unqualified to diagnose disease. He would advise him only to use his battery under the direction of a doctor." The jury returned a verdict in accordance with the medical evidence and added a rider embodying the coroner's remarks. This place, of course, is a quack institution pure and simple, but as in the present state of the law

such places are not illegal we have no more to say except that they should be made illegal and their owners or managers severely punished.

NATIONAL VACCINE ESTABLISHMENT.

THE National Vaccine Establishment, which is now located at the Local Government Board Offices at Whitehall, will on April 27th be removed to Room 140, St. Stephen's House, Cannon-row, Westminster. Supplies of lymph will be furnished to medical practitioners on personal application at the new premises between the hours of 12 and 2 P.M., or by letter directed to the Secretary at the new address.

THE DEGREE OF M.D. IN GERMAN UNIVERSITIES.

IN many of the German universities it has been usual to allow students who have not passed the State examination, which confers the right to practise, to take the degree of M.D. and it is by no means an unknown occurrence for a candidate possessing a university M.D. to be "plucked" at the State examination. Notwithstanding such failure, however, he is commonly addressed as "doctor" and is doubtless often taken for a qualified man. This ambiguous state of affairs is to be rendered impossible in future—at all events, in the Prussian universities, which will not after the commencement of next winter session permit candidates to obtain the M.D. degree until they are legally qualified. Leipsig and one or two other universities have a rule of this kind already.

SYMMETRICAL GANGRENE FROM EMBOLISM OF ONE ILIAC ARTERY.

AT a recent meeting of the Société Médicale des Hôpitaux M. Widal and M. Nobécourt brought forward a case of symmetrical gangrene produced by embolism of one iliac artery, a result which, though anticipated theoretically by some writers, does not appear to have been previously observed. A man, aged forty-five years, habitually in good health, suddenly felt in the night a sensation of numbness and coldness in the left leg. Two days later when he entered hospital the leg was absolutely cold and covered with purple patches which extended upwards as high as three fingers' breadth above the patella. There was slight tenderness in the course of the femoral artery in the triangle of Scarpa and no pulsation could be felt. The pulsations of the right femoral artery were quite distinct. Six days after the onset of the symptoms the right leg became affected. Suddenly the patient felt tingling and coldness in the leg, which became icy-cold and went through the same changes as the left. The pulsations of the right femoral artery became scarcely perceptible but did not disappear completely for three days. On the left side the patient began to experience acute pain especially in the great toe. The general condition gradually became worse, pyrexia, anorexia, diarrhœa, and nocturnal delirium appeared. There were no signs of visceral disease. Eighteen days after the onset of the symptoms pulsations returned in the femoral artery. The gangrenous changes progressed in the left limb but became arrested in the right a little below the patella. The patient died on the twenty-eighth day. The necropsy completely explained the clinical phenomena. In the left common iliac artery was an embolus adherent to the internal coat which appeared normal. Secondary but non-adherent clots were prolonged downwards into the internal and external iliac, the femoral, and the deep femoral, arteries. A secondary clot ascended to the bifurcation of the aorta and then descended in the right iliac and femoral, arteries. All the secondary clots were soft and non-adherent, those on the right side especially floated in the arteries which they did not fill. The left kidney and the spleen were full of infarcts of the same nature as the iliac embolus.

THE ROYAL HAMPSHIRE COUNTY HOSPITAL, WINCHESTER.

WE had occasion last week to refer to the resignation by the honorary medical staff of this hospital of their appointments. We are glad to learn that the resignations have been withdrawn, under which circumstances we think it right to withhold further comment.

THE PROSECUTION OF MR. H. K. HUNTER.

THE questions involved in this case—a full report of which will be found on p. 1075—are of great importance; but we must await the decision of the High Court before making any comment. The Society of Apothecaries, whose position is seriously affected by the magistrates' decision, are taking active steps to get the conviction quashed, it having been arranged before the case was heard that in the event of a conviction a case should be stated.

TUBERCULOSIS IN FISHES.

THE frequency of tuberculosis in cattle, especially milch cows, the extreme susceptibility of rabbits and guinea-pigs among rodents to artificial inoculation with cultures of the bacilli, and the occurrence of the disease both spontaneously and by accidental infection among fowls, have all been well-known for many years, but that fishes were susceptible does not seem to have occurred to anyone. M. Dubar, M. Bataillon and M. Terre, however, reported to the Académie des Sciences an instance of this which is not only probably unique, but presents several points of great scientific interest. The sputa and dejecta of a woman in an advanced stage of pulmonary and intestinal tuberculosis having been thrown into a fishpond many of the carp were observed to swell and die, and on examination their livers and spleens were found to be filled with tubercle bacilli. Others experimentally fed with tuberculous matter from human subjects, rabbits, and fowls died with the same appearances in two to three weeks and the bacilli of the diseased fish were equally infective to others which devoured them. But when ingested by, or inoculated into, rabbits and fowls the results were negative, the explanation being obviously that they had been so attenuated by cultivation in the colder blood of the fish as to have lost their virulence to warm-blooded animals. Fish must therefore be more susceptible than even rodents, though the conditions under which they live offer few opportunities for infection, those of the carp in a confined pond being, in fact, artificial. Under any circumstances, however, the danger of the communication of tuberculosis from the use of such fish as food must be infinitesimally small should this attenuation of the virulence of the bacilli be a constant phenomenon.

THE HANWELL SCHOOLS.

THE managers of the Hanwell Schools have recently received a report from the medical superintendent of the Isolation Hospital, Mr. Sydney Stephenson, with reference to the admission of ophthalmic cases to which they attach considerable importance, as the figures show that in the hospital only six ophthalmic cases were derived during a year from the Main School at Hanwell as compared with 144 cases sent from a contributary Union. The figures contained in the report deal with admissions during the twelve months ended on March 14th last, and the comparison is between (*a*) the children coming from Newington and Southwark in the St. Saviour's Union, and (*b*) the children transferred from the district schools, Hanwell. Mr. Stephenson

reports that 269 children remain in the Ophthalmic School, made up of 113 boys, 94 girls, and 62 infants. These children belong to the following unions, parishes, &c.: City of London, 2; St. Saviour's, 49; Bethnal-green, 37; St. Pancras, 35; Lambeth, 5; Hackney, 38; Islington, 6; Mile-end, 6; Forest Gate, 13; Poplar, 30; South Metropolitan School District, 5; Greenwich, 2; Shoreditch, 1; Kensington, 15; Strand, 5; Wandsworth and Clapham, 9; St. George's, 1; St. George's-in-the-East, 4; Fulham, 5; Lewisham, 1. The subjoined table shows, in parallel columns, month by month for the past year (*a*) the number of patients sent direct from St. Saviour's Union, and (*b*) the number of children admitted to the Ophthalmic School from the Main School:—

THE MEDICAL AND DENTISTS' REGISTERS.

WE have just received the Medical Register for 1898, from which it appears that the total number of registered practitioners with British qualifications is 34,642. In 1897 the total number was 34,478, being an increase of 877 over the total for 1896. The increase for this year over 1897 is, however, only 164, a most notable decrease and one which we are very glad to see. To go more into particulars, the new registrations are as follows: England, 670; Scotland, 425; Ireland, 135; total, 1230. In 1897 the total was 1385. The restorations to the Register for 1897 were 25, while in 1896 they numbered 52. The names removed by death in 1897 were 582 under Section 14, 504 under the penal clause 5, while in 1896 the numbers were respectively 532, 25, and 3. The removals under section 14 comprise those removed for not giving notice of change of address. We think it would add to the value of the Medical Register if a detailed obituary table were published, and also if the names of those removed from the Register under the penal clause were published. If it "is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners," it is surely also expedient that the names of those removed from the Register should be made accessible to those who require medical aid. We have also received a copy of the Dentists' Register for 1898, by which it appears that the number of those dentists practising in the United Kingdom as Licentiates in Dental Surgery is as follows, compared with the numbers for last year:—Royal College of Surgeons of England, 843 in 1898, and 785 in 1897; Royal College of Surgeons of Edinburgh, 181 in 1898 and 159 in 1897; Faculty of Physicians and Surgeons of Glasgow, 139 in 1898 and 130 in 1897; Royal College of Surgeons in Ireland, 451 in 1898 and 445 in 1897. Total for 1898, 1614. Total for 1897, 1519. Of those in practice before 1878, now practising with additional surgical qualifications, there are 34 for the year 1898, while for 1897 the number was only 30. Of those practising without any additional qualifications there are 3265 for the year 1898, while for the year 1897 the number was 3287. Of foreign dentists the numbers are the same for both years—namely, Doctor of Dental Medicine of the University of Harvard, 9; and Doctor of Dental Surgery of the University of Michigan, 15. It will be seen from these figures that the number of qualified dentists is increasing and the number of unqualified dentists is going down. The total number on the register for 1898 is 4937, while for 1897 it was 4860.

THE annual meeting of the American Medical Association will open at Denver, Colorado, on June 7th. The President is Dr. George M. Sternberg of Washington and the Secretary is Dr. W. B. Atkinson, 1400, Pine-street, Philadelphia. Denver is editorially described as being "one of the few large cities where the consumptive can live and thrive almost forgetful of his ailment."

MR. J. C. UMNEY, of the firm of Messrs. Wright, Layman, and Umney, Southwark-street, S.E., has been prompt in bringing out a short Guide to the New British Pharmacopœia, which contains many points that will be of service to the medical man as well as to the retail pharmacist.

WE learn that Sir Richard Thorne, who has been absent from his official duties at the Local Government Board for the last four weeks, is still unwell and is not likely to resume his work this month.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE report of the first part of the sixteenth sitting of the Royal Commissioners was given in THE LANCET of March 26th. The latter part of the sitting was occupied by the examination of Mr. Whitmore.

Mr. WHITMORE said he had been a member of the London County Council for three years, but had not served on the Water Committee. Both in his capacity as a Member of Parliament and as a county councillor he had given his attention to the question of the London water-supply and the conclusion at which he had arrived was that the London County Council as at present constituted was not fit to undertake the duties of Water Authority for London. He thought, however, that if purchase of the present undertakings of the water companies were carried out and if they were subsequently managed by a public authority that the London County Council, either nominally or virtually, must necessarily become that authority. Two years ago the Government had desired to create a Water Board for the whole of London, including not only the County of London, but the area within the jurisdiction of the county councils which made up the area of "Water London." On this Board the Government felt it necessary to give a preponderating voting power to the London County Council. Whether judged by the test of population or of rateable value the County of London must always have a preponderating voice on a Water Board which had control of the supplies for London. In the case of the Government proposal so much opposition was made by the outside authorities that the Government had to drop the Bill. The demand for control of the water-supply by a public authority was, in Mr. Whitmore's opinion, to a great extent a sentimental demand. To satisfy this sentiment it would be useless to purchase the present water companies' undertakings unless the London County Council became the managing and controlling body.

In answer to Sir JOHN DORRINGTON the witness admitted that he thought that the feeling in favour of purchase of the water companies' undertakings was founded partly on the idea that the companies now distributed large dividends to their shareholders and that a public authority would either diminish the charges paid for water or that there would be a lowering of the municipal rates. The other sentiment was of a political and theoretical nature and was

to the effect that a monopoly should be controlled and managed by a public authority.

Mr. WHITMORE thought it would be unwise to add to the local bodies in London, for there were already enough of them. If another were added to the secondarily elected bodies public sentiment in London would not be satisfied. The old Metropolitan Board of Works died "with universal satisfaction"; the Thames Conservancy is not a popular body; the Metropolitan Asylums Board is always being abused. The two latter bodies are elected by secondary not by direct methods. If, on the other hand, the new body were not so elected another directly elected body would be called into existence. At the present time, however, there is great difficulty in getting electors to go to the poll, and a new directly elected body was not wanted. Again, if a nominated paid body were appointed it would not satisfy the sentimental feeling to which he had alluded. It seemed, therefore, clear, the witness said, that if purchase were undertaken the London County Council must be the controlling authority.

The witness then proceeded to point out the purely political and partisan nature of the constitution and working of the London County Council, so that on any question of water-rate the Council would be sharply divided, and the division would be between the representatives of the wealthier districts and those of the poorer districts. The representatives of the poorer districts would not think of the ratepayers' interests but would think of the water consumers' interests. On the other hand in the wealthier districts the representatives would think more of the rates and less of the water-charges. The chief point, however, was that on both sides the members, instead of considering the business merits of the matter, would think of the next election and they would try in some way or other in not purely business ways "to gratify the hopes of the electors." "Therefore I myself," said Mr. Whitmore, "a friend of the London County Council, am really most earnestly anxious that this great business should not be handed over to us." In illustration of the manner in which the interests of the ratepayers are sacrificed by members of the London County Council Mr. Whitmore instanced the management of the Labour Department of the Parks Committee of the London County Council. The amount spent every year in wages for the employés in the parks has, he pointed out, mounted in a most significant way, and he was ashamed to say that on the Committee his own side, just as much as the other side, was absolutely unable to take a business view of the question.

In answer to Sir JOHN DORRINGTON the witness said both sides thought more of the voter than of the administration.

In answer to Mr. DE BOCK PORTER the witness said that the financial control rested with the Council itself and not with the Committee.

In answer to the CHAIRMAN the witness said that politicians were very bad councillors. The kind of men they wanted were business men of high character. Such people, unfortunately, were afraid of the amount of work which they would have to do on the Council and they disliked the trouble of a contested election.

The witness having again emphasised the political nature of the London County Council's proceedings said that a few members of the Council had always been of opinion that the purchase of the water companies' undertakings would not be successful. The bulk of the Moderate party doubtless agreed that purchase would be a good thing but they disagreed with the Progressive party as to the control of the undertakings. A section of the Moderate party was in favour of the Bill which the Government introduced two years ago for the creation of a water trust. That Bill broke down because the outside authorities would not support it, the reason of their opposition being that a preponderance of voting power was to be given to the London County Council.

Major-General SCOTT asked some questions with regard to the formation of a statutory committee for the purpose of purchasing the undertakings and suggested that if the Welsh scheme were carried out it would be necessary to consider the interests of the counties from which the water was taken and that if an aqueduct were made from Wales to London going through 200 miles of country it would be necessary to consider the interests of the people who were passed *en route*. He asked the witness whether he did not think that a statutory committee under the control of Parliament which represented all those interests would be a good body for managing the whole business.

Mr. WHITMORE said he did not think that such a body would be satisfactory to those who desired the purchase of the water companies' undertakings.

Major-General SCOTT pointed out that the authorities outside London who now share with London the same water-supply will in time be in want of an increased supply and asked whether they would not therefore inevitably be ultimately drawn into some general undertaking with the people of London.

Mr. WHITMORE said he did not know about that, but as a practical Parliamentarian he thought that no Government could legislate on the lines which he understood Major-General Scott to suggest. In answer to Sir GEORGE BARCLAY BRUCE he would not admit that no legislation which did not satisfy the London County Council would be possible or desirable.

The CHAIRMAN said that surely a proper supply of water for London was a question of interest quite independent of party. He might say, "A plague on both your houses." The question of the water-supply was of such importance that the Government might well take it in hand whether it pleased Progressives or whether it pleased Moderates, or pleased neither.

The witness admitted that they might do so, but he did not know how they would get on with their policy, and he did not know how they would pass their Bill. Speaking for himself the witness said he did not wish to see the financial difficulties of purchase faced. In his opinion grievances against the water companies were much exaggerated. He thought that the amalgamation of the companies would be a good thing. He suggested that the President of the Local Government Board should "benevolently conduct negotiations" with the chairmen of the water companies.

The CHAIRMAN asked what birch rod the President of the Local Government Board should have up his sleeve.

Mr. WHITMORE replied, "threatened legislation," and that the legislation should have reference to control. He said, however, that he had never understood what was meant by control.

The CHAIRMAN suggested that the London County Council might have taught the witness what they meant by control, which consisted amongst other things of cutting down dividends and reducing the amount of capital that had to be reckoned for dividend.

The witness said that he did not think the existing rights of the companies should be thus departed from, and that in his opinion control was not much wanted. He had lived in a good many houses in London and he had never been able to find a grievance against the water companies.

The seventeenth sitting of the Royal Commissioners was held in the Council Chamber of the Town Hall, Westminster, on Monday, March 28th. All the Commissioners were present. The first part of the sitting was occupied by the continued cross-examination of Mr. Whitmore.

Mr. WHITMORE said that he thought that the Unionist members of the London County Council would support a scheme for the constitution of a statutory committee on which representatives of the ratepayers would have a majority and in which also the other bodies interested would be represented. He thought that the companies should be amalgamated and a general water rate fixed for the whole of London. He would not oppose a scheme of purchase by a representative statutory committee. In any scheme of purchase he thought that the water companies should be fairly treated with regard to price.

In answer to Major-General SCOTT he said that in his opinion the Thames Conservancy and the Metropolitan Asylums Board were out of harmony with the popular sentiment because they were not popularly elected.

In answer to Mr. DE BOCK PORTER he said that he was convinced that the London County Council alone was not a fit body to be entrusted with powers over the water-supply.

Mr. ROBERT LEWIS said that inquiries had been going on for almost a century with regard to the London water-supply and asked the witness whether he thought it would be possible that any permanent settlement could be made if the companies' undertakings were not purchased. Mr. DE BOCK PORTER also remarked that it seemed curious that in the metropolis of the Empire the principal governing body should not be able to do what was done in provincial municipalities.

With regard to the future management of the London water-supply Mr. WHITMORE said that he thought it would

be an advantage if the companies would amalgamate and if they would reduce their charges for water. He thought that it was likely that the companies would voluntarily reduce their charges all round to the lowest rate now charged by any company out of fear of oppressive control or of confiscatory purchase.

The CHAIRMAN suggested that this was hardly a fair method of treating them and Mr. PEMBER said the suggestion amounted to a proposal that the water companies should commit suicide to save themselves from slaughter.

Mr. Whitmore's evidence was then completed by his examination by Mr. Balfour Browne, Q.C., on behalf of the London County Council.

Mr. G. PRIOR GOLDNEY, the City Remembrancer, was the next witness. He said that the City of London paid one-eighth of the rates of the metropolis and pointed out that in case of purchase the City would have to provide one-eighth of the purchase money; and in case of increase of the cost of supply one-eighth of the increased water charges and rates would fall to their share. From this it followed that the ratepayers of the City of London would have to pay very dearly for their water. Some years ago the Corporation of the City of London had introduced a Bill for the payment of water by meter. The witness suggested that at that time it was thought that meters could be obtained at the price of £2 each.

Mr. BAGGALLAY said that the cost of supplying meters to the whole of London was estimated at £3,000,000. The Bill did not pass.

The CITY REMEMBRANCER said that at the present time arrangements were made between the water consumers in the City and the New River Company with regard to individual cases. The witness was unable to find out how much was paid for water by the citizens of London, or how much water was supplied to them. The New River Company had declined to give that information and had described the City of London as "their little plum." In the case of a new building an arrangement was made by the proprietor with the New River Company as to the amount he should pay for water. Each case was treated on its own merits. The witness thought that in some cases the consumer paid about three-fourths of the full water rent and in some cases not more than one-half. He could not give information as to the number of supplies in which a reduction of the charge was made.—The CHAIRMAN asked whether it was one in a hundred or one in five, and in reply the witness said that although he could not give an accurate opinion he thought that probably in more than half the cases a reduction was made.

The Commission then adjourned until April 18th.

THE BRITISH PHARMACOPŒIA.

We have received a copy of the new British Pharmacopœia from the Registrar of the General Medical Council, who advises us that some little time will elapse before the book is issued to the public. Before proceeding to the detailed consideration of the volume it may be well to recall to our readers the history of its construction. The British Pharmacopœia is the modern representative of the Pharmacopœias of England, Scotland, and Ireland, or more correctly, perhaps, of London, Edinburgh, and Dublin. These, under Act of Parliament, were fused by a committee appointed by the General Medical Council and formed the basis of the first British Pharmacopœia, which was published in 1864. This volume consisted of two parts and an appendix, the first part devoted to materia medica, the second part to preparations and compounds, after which followed the appendix which dealt with articles employed in the preparation of medicines, articles employed in chemical analysis, test solutions for qualitative analysis, and test solutions for volumetric analysis. It is perhaps needless to go into the history of the conditions which led to the publication of a second edition so soon as 1867, but it may be pointed out that in the latter under the heading of "The Pharmacopœia" all articles and preparations officially employed in medicine were arranged in alphabetical order. In this edition doses were for the first time introduced and they were intended to represent average doses in ordinary cases for adults. These doses were not authoritatively enjoined by the Council and practitioners were informed that they must rely upon their own judgment and act on their own responsibility in graduating the doses of any therapeutic agents administered to patients. This edition was prepared by Professor Redwood of the Pharmaceutical Society and Mr. Warrington of Apothecaries' Hall, under the direction of five members of the Council, including the late Sir Richard Quain (then Dr. Quain), who acted as honorary secretary. An Addendum to the Pharmacopœia of 1867 was issued in 1874. In this Addendum several important new medicines were introduced, including nitrite of amyl, chloral hydrate, and pepsin. No indication was given of the names of those concerned in the production of this Addendum, which was merely published by the authority of the General Medical Council. A third edition was prepared in 1885, when three editors—Professor Redwood, Professor Bentley, and Professor Attfield—acted under the supervision of a committee of eight members of the Council, Sir Richard Quain acting as chairman, and five years later an Addendum edited by Professor Attfield was prepared under the general supervision of a committee of nine members of the Council with the same chairman. On this occasion the Council acknowledged the assistance afforded by various medical authorities and by the committee of the Pharmaceutical Society of Great Britain.

The present volume of the Pharmacopœia has been compiled under somewhat different conditions. Important aid has again been rendered by a large number of medical authorities and inquiries have been addressed to medical and pharmaceutical authorities in India and the Colonies. A committee of the Pharmaceutical Society has given valuable assistance, while the following referees have been consulted: in Chemistry, Dr. T. E. Thorpe, Dr. W. A. Tilden, and Dr. Emerson Reynolds; in Botany, Dr. W. T. Thiselton-Dyer and Mr. E. M. Holmes; in Pharmacology and Therapeutics. Dr. Lauder Brunton, Dr. Walter Smith, and Dr. Ralph Stockman. The task of editing the work has again been entrusted to Professor John Attfield, whose labours have been supervised by the following committee of members of the General Medical Council: Sir Richard Quain, Bart., M.D., President (chairman), Dr. Atthill, Mr. Brudenell Carter, Sir Dyce Duckworth, Dr. Leech, Dr. MacAlister, Dr. D. C. McVail, Mr. Tichborne, and Dr. (now Sir) John Batty Tuke, and a further innovation has been made by the appointment of Dr. Nestor Tirard as secretary of this committee. It will be seen, therefore, that on this occasion special measures have been adopted to ensure accuracy, not only in pharmacy, but also in chemistry, botany, pharmacology, and therapeutics and that the needs of the profession have at the same time been carefully borne in mind.

At first sight the volume which has been issued curiously resembles previous editions; it is practically of the same size as the edition of 1885, and the alphabetical arrangement of the contents has been followed as before. On closer investigation, however, it is found that the actual space occupied by the Pharmacopœia is considerably less, being 389 pages as compared with 472 of the 1885 edition, and this result has been attained by making very numerous omissions and very few additions. With regard to the additions, of which a complete list will be found at the end of this article, it will be seen that relatively few new drugs are included, the principal being salol, salicylate of bismuth, hyoscine hydrobromide, hyoscyamine sulphate, terebene, naphthol, and two preparations of thyroid. Most of the other additions consist of pharmaceutical preparations and of these a series of concentrated solutions are perhaps those which will be most acceptable to the medical profession, inasmuch as this innovation appears to constitute an attempt to keep pace with the dispensing practice of late years and to establish a standard of purity for many preparations which have hitherto been much employed with no certainty of their composition. Considering the small number of additions it is somewhat curious to find that there are no less than seven new syrups, most of which appear to be intended to render medicines more palatable.

Many of the decoctions have been removed from the Pharmacopœia, some perhaps as not being used, while others are replaced to some extent by the concentrated solutions. The omission of the strong solutions of ammonium acetate and of ammonium citrate will probably be regarded with mixed feelings, since there can be no doubt that these preparations are very largely employed, and it is certainly more convenient to store a solution of ammonium

acetate in a concentrated form. The solution of dialysed iron and the solution of bimeconate of morphine share the distinction of having been introduced in the 1885 edition of the Pharmacopœia and found not worthy of retention. It is not improbable that one or more of these four preparations may find a place in future Pharmacopœias. It is possible that the schedules of examination are partly responsible for the many other omissions. Examination schedules are drawn up from time to time and, in the opinion of examiners, indicate the drugs of therapeutic value; hence it can scarcely be a matter of surprise to find that these schedules influence the frequency of the employment of various pharmacopœial substances. Both with regard to omissions and additions the committee appears to have consulted the various examining bodies throughout the kingdom and the advice received is likely to have reflected the opinions of various examiners.

Those engaged in the compilation of the work are to be congratulated upon the moderation shown in the alterations of the names of Pharmacopœial articles and preparations. These alterations generally are in favour of greater chemical and pharmaceutical accuracy. Thus the green extracts left in the Pharmacopœia have their green character indicated by the suffix "viride," and in very numerous instances, of which perhaps the tinctura chloroformi et morphinæ is the best example, the addition of the suffix "composita" indicates the presence of more active ingredients than were formerly included in the title. It is satisfactory to note that the misleading name "ergotin" has been replaced by the more correct term "extractum ergotæ."

The same moderation is shown in the list of substances of which the composition has been altered. This list, moreover, indicates that respect for antiquity has not been allowed to bar pharmaceutical progress. For example, the committee has thought fit to alter the composition of articles of such established reputation as black draught, compound calomel pill, compound rhubarb pill, compound soap pill, and many other pills which are commonly used, as well as that of the aromatic powder of chalk and opium. It may allay some anxiety to say that the alteration in the composition of the pills frequently consists only in the substitution of syrup of glucose or some excipient for glycerin and that these alterations are necessitated by the growth of pharmaceutical knowledge. The proportion of active ingredients has not been altered. In some cases, as in the three hypodermic injections, the changes are more important. The hypodermic injection of apomorphine now contains one gramme in 100 c.c., the hypodermic injection of ergot contains thirty-three grammes of extract of ergot in 100 c.c., while the hypodermic injection of morphine contains five grammes of morphine tartrate in 100 c.c.; the strength of the last, therefore, is slightly less than a half that of the corresponding preparation in the 1885 edition. Many of the lozenges have been altered and there now appear in one of the Appendices four preparations which may be utilised as bases for lozenges—namely, a fruit basis of black currant, a rose basis, a simple basis of gum acacia and sugar, and a basis similar to the last, but flavoured with tincture of balsam of tolu.

An extremely important change consists in the tests applied for estimating the purity of different Pharmacopœial substances. Formerly the tests were described with no indication of the impurity sought for; thus we were told that certain substances should not give reactions with certain tests, but we were not told what impurities were present if reactions were obtained. Hence former Pharmacopœias to some extent presented a series of riddles, and, although it was satisfactory to know that no precipitate was obtained with certain reagents, it might sometimes be a little puzzling to guess what we were looking for and yet hoping not to find. To a great extent a contrary plan has been adopted in the present Pharmacopœia. Probable impurities are definitely mentioned under the description of each substance and the chemical tests for their detection are described once for all in one of the Appendices, instead of being scattered and repeated throughout the book. The length of the Appendices is thus necessarily greatly increased, but this increase is far more than compensated by the saving of space in the body of the Pharmacopœia.

Many of the pages in the Appendix dealing with the tests for substances mentioned in the text of the Pharmacopœia read almost like extracts from a work on practical chemistry For example, on one page we find grouped together under the heading of "Mercury" "reactions common to mercurous and to mercuric salts," "reactions characteristic of mercurous salts and of mercuric salts." The value of the book as a work of reference is thus enormously increased.

Considering the volume as a whole one of the greatest changes both in appearance and in constitution has been made in the preparation of the index. On former occasions the index was printed in double columns; by the use of italics synonyms were indicated and by the prefix of an asterisk the articles included in the Appendix could be readily distinguished. In the present edition we find that the names of the drugs are arranged in a single column and that these names are followed by three columns giving respectively the page, the dose, and the strength of the chief preparations, and, further, we find that under the English name of the drug is placed a list of its chief preparations and derivatives. The only indication of references to the Appendices is afforded by italic figures in the page column. The index forms the only place in the Pharmacopœia in which groups of official preparations are enumerated, and when its intention and scope are appreciated it is likely to be employed for the purpose of study, as well as for simple reference to the pages of the book, where more detailed information is to be found. The compilation of this index must have been a work of enormous labour and it appears to have been very carefully performed.

We have yet to mention many alterations which will materially affect the practice of those who have employed the former Pharmacopœia in their daily professional work. These are alterations in the strengths of many of the preparations. Some of these alterations unfortunately affect drugs which are in every-day use; thus at the head of the list stands aqua chloroformi, which is so extensively used as a vehicle. This preparation in the new Pharmacopœia is reduced to one-half of its former strength, so that it no longer affords an indication of the degree of solubility. The alcoholic extract of belladonna now contains one-third the proportion of the alkaloids present in average samples of the former extract and is prepared from the new liquid extract, instead of from the root. The extract of nux vomica now contains 5 per cent. of strychnine, which is two-thirds of the alkaloidal strength of the extract of nux vomica of the British Pharmacopœia of 1885, and this also is prepared from a liquid extract, instead of being obtained as formerly from the seeds. In this case the dose is the same as before, but the dose of the alcoholic extract of belladonna has been increased. The phosphorus pill of the last Pharmacopœia contained $\frac{1}{50}$ of a grain of phosphorus in 3 grains, or about 1 grain in 90. The new pill is made so that it may contain 2 per cent. of phosphorus and the whole method of preparation has been completely altered, carbon bisulphide being now employed as a solvent. The strength of the morphine suppositories has been reduced, each containing now a quarter instead of half a grain.

In the last Pharmacopœia there were 70 tinctures, in the new Pharmacopœia we find 67, and of those which have been retained from the former edition no less than 40 have had alterations in their strength. This large proportion of alterations of drugs in common use will not probably cause much inconvenience in practice, as the alterations in many cases are comparatively slight and appear to have been necessitated by the desire of bringing the dose of tinctures into line; in the preface it is stated that in the preparation of tinctures two chief objects have been kept in view, first to arrange for greater uniformity of dose, and secondly, to select for each tincture the menstruum that is best adapted to extract the active constituent. In the volume before us important alterations in strength are mentioned in paragraphs printed in small type. Such paragraphs are to be found under Tinctura Aconiti, Tinctura Chloroformi et Morphinæ Composita, Tinctura Colchici Seminum, Tinctura Lobeliæ Ætherea, Tinctura Podophylli and Tinctura Strophanthi. The alteration in the last mentioned is perhaps the most important. This preparation is now made with half the proportion of strophanthus ordered for the corresponding preparation in the additions of 1890, and the result is that the average dose of tincture of strophanthus is now made equal to that of tincture of digitalis.

It will be remembered that the doses in former Pharmacopœias were intended to represent the average range of doses for adults and the volume has often been charged with not acting up to its intention in this respect, some doses having been much larger and others much smaller than those ordinarily employed. In general terms it appears that the doses in the new Pharmacopœia have been carefully

modified so as to represent more perfectly the practice of the profession and the result is that in most cases the doses are now smaller than before. At the same time it must be remembered that the doses are not officially enjoined and that they merely indicate the range of safety applicable to patients whose previous history is unknown, and they do not prevent the employment of much larger doses on the responsibility of the prescriber.

From the above account it will be seen that the compilers of the new Pharmacopœia have done their work with considerable boldness and that they have greatly enhanced the value of the book. They have deleted much that weighed down former volumes and lent an air of antiquity that was almost open to the charge of senility, and at the same time they have been careful to avoid giving the stamp of authority to those numerous substances which have scarcely yet established fair claims for recognition. The names of many drugs which might have been included will probably occur to our readers and a certain proportion even of those found in the present volume might yet have been deleted with advantage, but on the whole the work has been well done and as a standard of purity it presents a very great advance on former Pharmacopœias. The diction employed, more particularly in the description of botanical substances, still appears somewhat archaic, but these substances are described in terms which are more in accordance with good specimens which find their way into the market, while in indicating the botanical sources the committee has had the advantage of the advice of well-known experts. In all probability some of the details of methods of preparation may be found to require modification, since pharmaceutical methods proverbially do not always succeed in different hands; but we think that members of the profession have reason to be grateful for the careful work which has been put before them and that future practitioners will find that the range of their resources is largely increased by the simplification of dosage.

When dealing with such a work as the Pharmacopœia, issued by the authority of a council and prepared by an editor under the supervision of a committee, it would be invidious to attempt to congratulate individuals upon their labours; but where such great changes have been made in the book it is surely permissible to assume that some of the new workers are largely responsible for these alterations and it is worth noting that the new members of the committee are Dr. Leech, Dr. MacAlister, Dr McVail, and Mr. Tichborne and that another innovation consists in the employment of Dr. Tirard as secretary; it therefore seems possible, or even probable, that many of the fundamental changes above mentioned must be due to their labours.

LIST OF ADDITIONS.

Araroba.
Aurantii cortex recens.
Benzol.
Bismuthi salicylas.
Caffeinæ citras effervescens.
Caoutchouc.
Carbonis bisulphidum.
Cocaina.
Codeinæ phosphas.
Extractum belladonnæ liquidum.
Extractum ipecacuanhæ liquidum.
Extractum jaborandi liquidum.
Extractum nucis vomicæ liquidum.
Extractum strophanthi.
Glycerinum acidi borici.
Glycerinum pepsini.
Hydrargyri oleas.
Hyoscinæ hydrobromidum.
Hyoscyaminæ sulphas.
Infusum scoparii.
Kaolinum.
Lamellæ homatropinæ.
Liquor calumbæ concentratus.
Liquor caoutchouc.
Liquor chiratæ concentratus.
Liquor cusparіæ concentratus.
Liquor ethyli nitritis.
Liquor hamamelidis.
Liquor hydrogenii peroxidi.
Liquor kramerіæ concentratus.
Liquor morphinæ tartratis.
Liquor pancreatis.
Liquor picis carbonis.
Liquor quassiæ concentratus.
Liquor rhei concentratus.
Liquor sarsæ compositus concentratus.
Liquor senegæ concentratus.
Liquor sennæ concentratus.
Liquor thyroidei.
Lithii citras effervescens.
Morphinæ tartras.
Naphthol.
Oleum pini.
Oleum rosæ.
Paraffinum liquidum.
Physostigminæ sulphas.
Pilula quininæ sulphatis.
Pix carbonis præparata.
Pruni virginianæ cortex.
Quillaiæ cortex.
Quininæ hydrochloridum acidum.
Salol.
Spiritus anisi.
Strychninæ hydrochloridum.
Suppositoria acidi carbolici.
Suppositoria belladonnæ.
Syrupus aromaticus.
Syrupus calcii lactophosphatis.

CLIFTON GRAND SPA AND HYDROPATHIC ESTABLISHMENT.—The formal opening of the Clifton Grand Spa took place on March 30th. The building, which is probably one of the best of the kind in England, has been designed to compete with the Continental spas. At the public reception which followed Dr. Shingleton Smith replied for the medical profession.

THE GENERAL MEDICAL COUNCIL AND THE "L.S.A."

A PROSECUTION by the General Medical Council came before the Petty Sessional Court at Caxton, Cambridgeshire, on April 6th, in which a medical man was charged with wilfully and falsely pretending to use the name and title of physician and surgeon contrary to Act 21 Vict. c. 90, sect. 40, and Acts amending the same. The defendant was Mr. Herbert Kingsley Hunter, of Montague House, Gamlingay, Cambridgeshire, who a few years ago acquired the practice formerly carried on for many years by Dr. Trimmer.

Mr. Muir Mackenzie, barrister, instructed by Mr. H. Farrer, of Lincoln's Inn-fields, appeared for the General Medical Council, whose solicitor, Mr. F. W. Farrer, had laid the information, and Mr. Horace Condy, barrister, instructed by Messrs. Berkeley, Son, and Hains, of Lincoln's Inn-fields, appeared for the defendant.

Mr. MUIR MACKENZIE, in opening the case for the prosecution, said the facts were not in dispute. Mr. Hunter, the defendant, was an American citizen who came over to this country to practise, and in November, 1893, obtained the degree or qualification of a Licentiate of the Society of Apothecaries of London and was registered as such. That was the only English qualification which Mr. Hunter possessed, but he claimed to possess, and no doubt rightly, an American degree of Doctor of Medicine (Philadelphia). In his practice he assumed, and to do him justice he claimed the right to assume in this country, the title of "M.D." and also "physician and surgeon." The General Medical Council warned Mr. Hunter that he was practising under a title which he did not possess. In reply Mr. Hunter asserted that he had a right to do so and therefore this was not a case of assuming a title inadvertently or through ignorance. It had been decided by the courts of law, in the case of Regina *v.* Baker, that a medical practitioner who was a Licentiate of the Society of Apothecaries and had no other registered title had no right to practise under the title of "physician and surgeon" or "M.D.," but had the right to practise under the title only which he did possess—viz., that of "L.S.A." To show that Mr. Hunter took the course he had done in order to assert his right he (Mr. Mackenzie) read some letters which had passed between Mr. Hunter and the General Medical Council in the last of which the defendant wrote to the Council: "I shall not trouble you further with any questions, but as I am backed up I mean to fight now to the end." In conclusion he (Mr. Mackenzie) should call evidence to show that Mr. Hunter did use the titles of physician and surgeon when it was perfectly clear that he was not entitled to do so. If Mr. Hunter claimed to do it under the diploma of the Society of Apothecaries or the American degree, then the law had held by the decision in the Aston case that he was wrong, and he must ask the Bench to convict if they were satisfied that the defendant had used the titles of physician and surgeon. He then put in a copy of the Medical Register, which is made evidence by the statute, and called witnesses.

Mr. HERBERT WILLIAM FARRER, of Lincoln's Inn, son of Mr. F. W. Farrer, solicitor to the General Medical Council, formally proved the receipt of the letters from Mr. Hunter to the Council and said Mr. Hunter was first warned that he must not use the title "M.D." and he asked if he could use physician and surgeon and was informed that the Council could not advise him.

Witnesses were called as to paying accounts to Mr. Hunter, printing of bill-heads, &c., in which he described himself as "M.D.," and as "L.S.A., physician and surgeon."

Mr. CONDY, for the defence, said the title "M.D." had nothing to do with this case and the case of the Queen *v.* Baker was for using "M.D."

Mr. MACKENZIE said it was also for using "physician and surgeon."

Mr. CONDY said the defendant did not claim the right to use the title of "physician and surgeon" by virtue of the American degree but by virtue of the diploma which he held from the Society of Apothecaries, which he (Mr. Condy) handed to the Court. In 1886 the Society of Apothecaries was empowered to grant diplomas entitling their holders to practise in medicine, surgery, and midwifery and it was by virtue of that diploma, and by that alone, that Mr. Hunter claimed the right to use the title of "physician and surgeon." Upon his bill-heads he described himself as "L.S.A., physician and surgeon," and it was of this that the prosecution complained. The M.D. degree was not before them at all. He submitted that "L.S.A., physician and surgeon," was an accurate description which could deceive no one, because "physician and surgeon" being prefixed by "Licentiate of the Society of Apothecaries" showed the right upon which he practised. The case of the Queen *v.* Baker turned chiefly upon the M.D. degree and he referred to the case of Ellis *v.* Kelly in support of his view that the diploma gave the defendant the right to use "physician and surgeon" in connexion therewith. The correspondence put in showed that when Mr. Hunter was told that he could not use M.D. he ceased to use it; that he asked the General Medical Council if he could call himself "physician and surgeon," and when they replied, "We cannot advise you," he did the reasonable thing of applying to the body under the diploma of which he was entitled to practise—the Society of Apothecaries. Their answer was that a "L.S.A." could call himself by any title or titles denoting the right to practise in medicine, surgery, and midwifery providing that he did not assume titles conferred by another governing body or university. He therefore submitted that the defendant had the right to describe himself as he had done. If the magistrates were against him on that point then he submitted that before they could convict the defendant they must also make up their minds that he not only called himself that which in fact the law would not allow him to do, but that he did so wilfully and in violation of the law and knowing that he had no right to do so. Lord Bramwell had held that the statute did not impose a penalty for incorrectness merely, but for assuming a title wilfully and falsely. The Act was intended to apply to unregistered men and he submitted that his client had a right to describe himself as he did and that they could not convict him of wilfully or falsely pretending to be that which he was not.

The Bench decided to convict upon the information for styling himself a "physician" and imposed a fine of £5 and costs. The second information for calling himself a "surgeon" was not proceeded with.

Mr. CONDY asked the magistrates to state a case. It was important that this should be done both for the Society of Apothecaries and the General Medical Council. The matter must be fought out because the Society of Apothecaries must defend their diploma.

The magistrates saw no objection to a case being granted and it was understood that the necessary steps would be taken for carrying the case to a superior court.

THIRD REPORT TO THE REGISTERED PRACTITIONERS OF ENGLAND AND WALES.

LADIES AND GENTLEMEN,—The brief session of the General Medical Council which has just closed has been to a very gratifying extent productive of much good to the profession at large, not only in regard to the subject laid before the Council for its discussion—viz., the midwives registration question—but also in establishing more firmly the principles of defensive medical legislation.

In the session of November last year the Council appointed a committee composed as follows: Sir Richard Thorne Thorne (chairman), Dr. Atthill, Dr. Glover, Dr. Cameron, Mr. Carter, Mr. Brown, and myself, to report upon any Bill bearing on the subject of midwives' registration that might be brought before Parliament and referred for criticism to the Council by the Government (Privy Council).

When Mr. J. B. Balfour's Bill was introduced and immediately obtained an early place in the ballot I wrote to the chairman and urged that the committee should be called together. After considerable opposition my request was acceded to. The committee met on three occasions and drew up a report, which has just been published *in extenso* in the medical journals. This report was practically based upon the general principles formulated two years ago by the Midwives Bill Sub-committee of the Parliamentary Bills Committee of the British Medical Association.

Of these principles the first and most fundamental is that the only possible method of arresting the notorious evils committed by midwives at the present time is to provide that an ignorant person who practises as a midwife for gain shall be punished. The second principle is that the trained midwife shall be limited to the attendance of cases of natural labour only, and shall tend as a nurse the mother and child during the lying-in period.

The third principle is that there shall be instituted a proper system of supervision and teaching of midwives or midwifery nurses by the medical profession. The report of the committee to the Council naturally met with obstruction in the committee from those members who are opposed to medical reforms but who did not venture in the Council itself to give expression to their antagonism.

All the principles of the committee's report were unanimously adopted by the Council and cast in the form of a memorandum (with wording adopted from the committee's report). This memorandum was directed to be sent to the President of the Privy Council as the Council's answer to a letter which had been received from him requesting the observations and opinions of the Council upon Mr. J. B. Balfour's Bill.

Inasmuch as this memorandum of the opinions of the Council is, like the committee's report, a categorical condemnation of Mr. J. B. Balfour's Bill, nothing can be more satisfactory to the profession than the obtaining from the Council of a unanimous denunciation of a Bill which not only afforded no protection to the public, but seriously threatened the lawful rights of the registered medical practitioner. At the same time I wish to particularly draw the attention of the profession to a very important point involved in this decision—viz., that now the General Medical Council has officially accepted the principle laid down by the committee that no unqualified person should practise with impunity for gain. It necessarily follows as a logical sequence that this step in advance involves the support of the Council to future legislation which may be brought forward for the strengthening of the Medical Acts in this direction, and the earnestness of the feeling of the Council upon the matter was displayed in so unmistakeable a manner that the opposite view to which such strong expression has recently been given in the medical press, found upon this occasion absolutely no exponent.

April 12th, 1898. VICTOR HORSLEY.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6197 births and 4352 deaths were registered during the week ending April 9th. The annual rate of mortality in these towns, which had been 20·2 and 21·5 per 1000 in the two preceding weeks, declined again last week to 20·2. In London the rate was 19·6 per 1000, while it averaged 20·7 in the thirty-two provincial towns. The lowest death-rates in these towns were 12·6 in Portsmouth, 14·1 in Oldham, 14·7 in West Ham, and 15·3 in Cardiff; the highest rates were 23·4 in Derby, 23·5 in Leeds, 23·7 in Plymouth, 25·6 in Salford, and 27·7 in Liverpool. The 4352 deaths in these towns included 516 which were referred to the principal zymotic diseases, against 550 and 538 in the two preceding weeks; of these, 234 resulted from measles, 125 from whooping-cough, 57 from diphtheria, 34 from "fever" (principally enteric), 33 from scarlet fever, and 31 from diarrhœa. The lowest death-rates from these diseases were recorded in Blackburn, Preston, Norwich, and Derby; and the highest rates in Sheffield, Brighton, Bristol, Swansea, and Leicester. The greatest mortality from measles occurred in Brighton, Swansea, Bristol, Leicester, Oldham, Halifax, and Sheffield; from whooping-cough in West Ham, Bolton, and Salford; and from "fever" in Burnley. The mortality from scarlet fever showed no marked excess in any of the large towns. The 57 deaths from diphtheria included 29 in London, 3 in Cardiff, 3 in Bristol, 3 in Birmingham, and 3 in Leicester. One fatal case of small-pox was registered last week in Leeds and 1 in Gateshead, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals on Saturday last, April 9th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2419, 2371, and 2377 at the end of the three preceding weeks, had further risen to 2421 on Saturday last; 234 new cases were admitted during the week, against 255, 191, and 239 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 402 and 451 in the two preceding weeks, declined again to 372 last week, and were 10 below the corrected average. The causes of 59, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Salford, Bradford, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Blackburn, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·9 and 24·2 per 1000 in the two preceding weeks, declined to 24·1 during the week ending April 9th, but was 3·9 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·0 in Perth and 17·6 in Edinburgh to 26·3 in Glasgow and 31·9 in Dundee. The 728 deaths in these towns included 44 which were referred to whooping-cough, 24 to measles, 20 to diarrhœa, 9 to diphtheria, 4 to "fever," and 4 to scarlet fever. In all, 105 deaths resulted from these principal zymotic diseases, against 73 and 82 in the two preceding weeks. These 105 deaths were equal to an annual rate of 3·5 per 1000, which was 1·1 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 25 and 21 in the two preceding weeks, rose again to 44 last week, of which 31 occurred in Glasgow, 4 in Paisley, 3 in Aberdeen, and 3 in Edinburgh. The 24 deaths referred to measles exceeded by 1 the number in the preceding week, and included 21 in Glasgow. The fatal cases of diphtheria, which had been 3 and 4 in the two preceding weeks, further rose to 9 last week, of which 2 occurred in Glasgow, 2 in Aberdeen, and 2 in Greenock. The 4 deaths referred to different forms of "fever" included 2 in Glasgow and 2 in Edinburgh; and of the 4 fatal cases of scarlet fever 3 were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 175 and 178 in the two preceding weeks, declined to 157 last week, but slightly exceeded the number in the corresponding period of last year. The causes of 36, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·5 and 35·1 per 1000 in the two preceding weeks, declined again to 24·3 during the week ending April 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 32·4 per 1000, the rate during the same period being 21·7 in London and 20·3 in Edinburgh. The 163 deaths registered in Dublin during the week under notice showed a decline of 72 from the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 11 and 20 in the two preceding weeks; of these, 3 resulted from different forms of "fever," 2 from diphtheria, 2 from whooping-cough, and 2 from diarrhœa, but not one from measles, scarlet fever, or small-pox. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 2·8 in London and 1·8 in Edinburgh. The deaths referred to "fever," which had declined from 7 to 4 in the three preceding weeks, further fell to 3 last week. The fatal cases of whooping-cough, which had been 3 and 5 in the two preceding weeks, declined again to 2 last week. The mortality from diphtheria and from diarrhœa also showed a decline from that recorded in the preceding week. The 163 deaths in Dublin last week included 21 of infants under one year of age, and 39 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons were below those recorded in any recent week. No inquest cases or deaths from violence were registered; and 58, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL LEWIS A. IRVING retires on retired pay. Brigade-Surgeon-Lieutenant-Colonel Andrew A. Macrobin retires on retired pay. Surgeon-Lieutenant Browne-Mason and Surgeon-Lieutenant Penny join at Woolwich for duty. Surgeon-Major McCormack embarks for West Africa. Surgeon-Major O. E. P. Lloyd, V.C., is posted to Maryhill, Glasgow, in charge of the Station Hospital. Surgeon-Lieutenant-Colonel Fenn is ordered to Dover for duty. Surgeon-Major James has left the Home District for duty at Aldershot.

INDIA AND THE INDIAN MEDICAL SERVICES.

The following officers have been transferred: Surgeon-Major Barry, Civil Surgeon, from Mussorie to Gorakhpur, and Surgeon-Lieutenant-Colonel Moran, Civil Surgeon, from Gorakhpur to Mussorie. The services of the under-mentioned officers are placed permanently at the disposal of the Government of Bengal: Surgeon-Captain Deare, Surgeon-Captain Oldham, and Surgeon-Captain Bird. The services of Surgeon-Colonel Hay (Bombay) are replaced at the disposal of the Military Department. Surgeon-Major Quayle, Civil Surgeon, Nimar, is placed in Visiting Medical Charge of Hoshangabad until further orders.

YEOMANRY CAVALRY.

Royal 1st Devon: Surgeon-Captain F. Morgan resigns his commission. Herts: John Andrew Turner, M.B. Edin., to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Newcastle-on-Tyne (Western Division, Royal Artillery): Surgeon-Captain A. T. Wear, M.D. Durh., to be Surgeon-Major. 1st Northumberland (Western Division) Royal Artillery: Surgeon-Lieutenant J. Wreford to be Surgeon-Captain. *Rifle:* 1st Volunteer Battalion the Northamptonshire Regiment: Surgeon-Captain R. Greene resigns his commission.

CASUALTIES IN MODERN SEA FIGHTS.

The report which was read at the Moscow Congress by Mr. S. Suzuki, fleet-surgeon in the Imperial Japanese Navy, and which was printed at length in THE LANCET of Oct. 16th, 1897, contains a great deal of interesting information about Wei-hai-wei which now becomes topical and to which we refer our readers. When Wei-hai-wei (pronounced *way-high-way*) was taken in February, 1895, 12 ships of the attacking fleet, which consisted of 25 large vessels besides 15 torpedo boats, were struck by 28 projectiles, but the resulting loss was not very great, only 20 of the Japanese having been killed and 46 wounded. The percentage of casualties in each grade was as follows:—Officers, 10·0; non-commissioned officers, 1·0; engineers and stokers, 0·6; bluejackets, 1·2; non-combatants, 0·6. During the Yalu engagement 125 missiles of various kinds reached the Japanese ships, the percentage of killed and wounded in this case being officers, 7·8; non-commissioned officers, 8·7; engineers and stokers, 2·6; bluejackets, 9·4; non-combatants, 9·8. At the beginning of the fight a single projectile, 30 centimetres in diameter, killed 30 men on board the *Matsushima* and wounded 70 more. On board the *Hiyei* a shot of similar dimensions killed 14 men and wounded 27, without reckoning 10 more who were injured by splinters. On board the *Itsukushima* 8 men were killed and 3 wounded by a projectile of 21 centimetres; 5 stokers were severely wounded by a 15-centimetre shell which penetrated the starboard coal-bunker 3 ft. above the water line; and a smaller shell, only 5 centimetres in diameter, sufficed to place 10 sailors *hors de combat*, 4 of them with mortal wounds. On board the *Akitsushima* 5 men were killed and 9 wounded by a 21-centimetre projectile; and on the *Fusoo* 10 men were disabled by the fragments of a shattered chimney-stack. The *Saikyo* was more fortunate than the above-mentioned vessels, for although her hull was penetrated several times by the largest-sized missiles she nevertheless suffered comparatively little damage as none of them exploded. The torpedo-boats seem to have gone through both engagements without injury from the enemy with the exception of No. 9, which was hit no fewer than thirteen times at Wei-hai-Wei on Feb. 5th. Most of the shots were harmless, but one shell exploded in her boiler and caused the death of eight men by scalding. The Japanese surgeons one and all treated their wounded antiseptically in the most enlightened fashion and with the happiest results. One man died from erysipelas, but this was the only preventable complication which occurred. They also practised the most strict conservatism in their operations, amputations being performed solely as a last resource in cases where the larger blood-vessels were implicated or where articulations were entirely disorganised. In many instances joints that had been penetrated were preserved at the expense of more or less complete ankylosis; 21 per cent. of the total injuries were situated on the head; and in the next place the parts affected were the upper and the lower extremities. Then in their order came wounds of the abdomen, the chest, the back, and finally the neck. Several cases of ruptured tympanum were due to the heavy ordnance.

PUBLIC HEALTH OF GIBRALTAR.

We have received a copy of the Annual Report on the Public Health of Gibraltar for 1897 by Surgeon-Major H. P. G. Elkington, M.R.C.S. Eng., D.P.H., of the Army Medical Staff, who is acting as medical officer of health at that station. Although the military population and the non-residents and persons entering Gibraltar on daily permit are not included in this report there are several matters of more or less interest to all. The nature and amount of the water-supply, for example, will always have an interest for the garrison of a place liable to be attacked and besieged. The civil community in Gibraltar exists under peculiar conditions which make it difficult to form an accurate estimate of the population, but the Census returns for 1891 show a total civil population of 19,100, composed of a "fixed" and "resident alien." The death-rate in 1897 was 23·56 per 1000 of the total population and 25·43 per 1000 of the "fixed" population. These rates were in excess of those of the past two years and of the previous quinquennial period. The infantile mortality (under one year of age) is high—it was 184·9 per 1000 in 1897—and the death-rate among children under five years of age was equal to 108·11 per 1000. The principal causes of death were zymotic and respiratory diseases. Measles, small-pox, diphtheria, diarrhœa, fevers, and respiratory and tuberculous affections appear to be the main prevailing diseases at Gibraltar. The sanitary condition of Gibraltar is improving but much still remains to be done. There is a good deal of overcrowding and this still continues to be the great problem to be dealt with. A bacteriological laboratory was opened at Gibraltar in 1896 and has done good work.

HOSPITAL STOPPAGES.

The *Broad Arrow* states that "in the case of soldiers (including boys) admitted into hospital on account of injuries received when in the execution of their duty or sickness, certified by the medical officer to have been contracted as a direct result of their military service, the circumstances being beyond the soldier's own control, one half of the hospital stoppage may be remitted by the general officer commanding. If any injury has been received when on duty at drill or manœuvres under circumstances beyond the soldier's own control the whole stoppage may be remitted."

DEATHS IN THE SERVICES.

Surgeon-Captain Edward Corcoran, A.M.S., on March 23rd, at Okuta, in the Hinterland of Lagos, aged twenty-five years. He contracted malarial fever while on field service. He joined the Army in the month of February, 1887, and served in the Ashanti Expedition of 1895–96 (star).

THE QUEEN'S BIRTHDAY.

It is notified in the *London Gazette* that "the Queen's Birthday will be celebrated in London alone on Saturday, May 21st next, and at all other stations, naval and military, on Tuesday, May 24th next."

BRISTOL ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual meeting of this institution was held on April 4th, under the presidency of the Bishop of Bristol. The report showed that during 1897 there had been 709 children treated as in-patients, and 1069 women and 2602 children were attended as out-patients. The financial statement showed an adverse balance of £994. Sir W. H. Wills Bart, M.P., had given £250 for the convalescent home at Weston-super-Mare in connexion with the hospital.

"Audi alteram partem."

THE CROWN VACANCY IN THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—I feel I am asking a great favour to be allowed to add a few words to the leading article on the above subject in your last issue, but our case is urgent, and therefore beg to be allowed to point out its urgency. Everybody must agree that the two classes needing representation are the dentists and the general practitioners, but I venture to think the former have the greater claim, and for the following reasons. The general practitioner is already ably represented in the person of Dr. Glover, while the dentist has nobody to speak with authority on his behalf. No period of time can add to the dentists' claim, because it is as urgent now as it has always been.

In 1878 when the Dentists Act was passed Sir John Tomes advocated the appointment of a dentist, and yet in twenty years one has not been appointed. At the present time the question of the dental curriculum is under consideration and the advice of a dentist would be of inestimable value in arriving at a conclusion. That one-sixth of the cost of the office is borne by the Dental Fund appears to be an additional reason for such an appointment. A careful search through the Medical and Dental Acts shows that without an additional Act of Parliament the number of the General Medical Council cannot be increased and it is therefore only possible for a dentist to be nominated by the Crown. It surely is not justice for the Dentists Act to be administered by the General Medical Council when there is nobody on the Council able to speak with authority and experience on behalf of its interpretation. The gentleman suggested by the British Dental Association as the Dental Representative would certainly add lustre to that already distinguished body, the General Medical Council.

I am, Sirs, your obedient servant,

MORTON SMALE.

April 12th, 1898. Dean, Dental Hospital of London.

NEW DRUGS AND PREPARATIONS.

To the Editors of THE LANCET.

SIRS,—It is a remarkable fact that sixty years ago, when we had great faith in drugs and used them largely, they were very few and simple and that now, when we trust much more to nature, hygiene, and nursing, we are inundated with them so that samples of new drugs and preparations are becoming quite a nuisance. Almost every day the post brings me one or more of them, with pamphlets and testimonials, and a request that I will test them by prescribing them for my patients. I must have received hundreds of samples in the last few years and have never prescribed one of them, but I have quite a museum of these curiosities at the Surrey Dispensary, where they are kept unopened. As interesting specimens of nomenclature I may mention cotoine, migrainin, amydol, lycetol, nosophen, neboline, gelanthe, terrol, coumarin, eikonogen, eugenol, gallonal, glutol, loretin, terpinol, cosmoline, ozokerine, kreachyle, urecide, psonal, and seng. As these things are very seldom prescribed of course the dispensing chemist does not *stock* them, so that when they *are* prescribed he has to purchase them in quantities much larger than he requires and, as many of them are never prescribed a second time, the surplus represents so much money lost. For example, I know a chemist who had a prescription in which cotoine was ordered; he had to pay 30*s.* for an ounce of it, used about a shilling's worth, and lost 29*s.* by this one prescription. When physicians prescribe such things I think they should supply the chemist with the samples they have received from the wholesale houses, otherwise they are impoverishing a class of men already poor enough and who are very much underpaid for their education, skill, time, and trouble. Then, as I said, we are asked to test all these new preparations. Now, to test any one of them fairly and scientifically we should require a ward of at least 20 beds and 20 typical cases of the disease it is said to cure; we should then give the preparation to 10 patients, treat the other 10 without it, and compare results. If all the samples we receive were thus tested we should have to give up practice and devote every hour of our lives to the work. I hope the new Pharmacopœia will give us all the drugs and preparations new and old that we can possibly require so that we need never prescribe anything outside of it. Physicians' prescriptions would then be simple and intelligible and chemists would not lose money by dispensing them.—I am, Sirs, yours faithfully,

D. HOOPER, B.A., M.B.Lond.,
Physician to the Surrey Dispensary.

Trinity-square, S.E., April 1st, 1898.

"SICK AND OBSTETRIC NURSES BILL."

To the Editors of THE LANCET.

SIRS,—In your review of this Bill on page 953 of THE LANCET of April 2nd, 1898, you ask: "Suppose a voluntary nursing association were to adopt this Bill, would such an association obtain the assistance of the relieving officers and would the relieving officers investigate cases and make reports to the voluntary association as they would to their board of guardians?" My reply to both queries is an emphatic negative. It is distinctly laid down in Clause 5, sub-clause *c*, "that in order to make due provision for the sick and parturient poor and their children it shall be incumbent upon boards of guardians, *in default of other authority*, to adopt and carry out the provisions of this Act in their respective unions and to vote the necessary funds or to make grants in aid to voluntary nursing associations to meet the expenses of the provisions of this Act." And this provision is worked out in Schedule D on the basis of the local nursing association to which the Richmond board of guardians already contribute with the sanction of the Local Government Board. Under Clause 8 relieving officers would, of course, report to their boards, who would issue "the orders" to the three classes of poor persons specified therein, and under this clause the fees would be the same as under the consolidated orders, with mileage extra, but the fees and contributions under a nursing association would be as contained in Schedule D.

I may repeat that the intention throughout the Bill is the establishment of voluntary nursing associations on the lines of those already existing in various parts of the country. Assistance by way of subsidy is only claimed for those that would not be self-supporting. You may not have noticed that Mr. Gerald Balfour announced in the House of Commons recently that he hoped to be able to introduce "a Bill to enable boards of guardians in Ireland to subscribe to nursing institutions for the benefit of the sick poor in their districts." This is a direct and opportune acknowledgment of the principles of my Bill from an unexpected quarter.

The Bill, as you say, may not "wholly meet the case," but of the Bills now before the profession it is the *only* one that attempts to provide for the needs of the "sick and parturient poor," the others being taken up with the registration of midwives, which, according to the promoters, is quite a different question and by no means intended to meet the urgent wants of "the poor."

I am, Sirs, yours faithfully,

East Sheen, April 9th, 1898. ALEXANDER MCCOOK WEIR.

THE EPIDEMIC OF MEASLES.

To the Editors of THE LANCET.

SIRS,—The hope that the public will learn from the present epidemic of measles the gravity of the disease so well expressed in your leading article of March 26th I can fully endorse from an epidemic I experienced in 1894. In November and December of that year an outbreak occurred in this town. The power of it can be readily understood from the following facts. My practice was one of three, and I attended, independently of the other practitioners, 157 cases, and I had 13 deaths in the two months, the population of the entire parochial area being only just outside 3000. The Christmas was a most melancholy one, and one not easily forgotten, 7 children had been buried the Sunday before Christmas day and several were lying dead then. Every day, and nearly all day, the church bell was tolling for deaths or funerals. I attribute the high mortality of this

epidemic to two chief factors: first, the presence of lumbricoides in about 90 per cent. of the cases, as verified by their escape; and, secondly, that in about half the number of cases the houses were devoid of fireplaces in the bedrooms. With regard to the worms I found that an infant of ten months voided *eight* of them, all measuring over 6 in. in length. They seemed unable to remain comfortably in their host when the initial rise of temperature occurred and escaped either from the mouth or per anum. If all escaped the case generally did well, but if some remained they died, decomposed, and set up a toxæmic condition with a secondary rise of temperature to 104°, 105°, or even 107°, accompanied by rapid, shallow breathing and some delirium. The breath developed a characteristic and peculiar putrid smell and the tongue was covered with a white fur with prominent reddened papillæ. Sleeping in a fireless room at this period of the disease would be a menace to the child's life, but many did so even in frosty nights; broncho-pneumonia usually supervened. Among the lower classes the child had been treated up to this point, generally speaking, by the parents, the rural mind having a strong belief in the internal administration of "sum hot zyder" and piling weighty clothes upon their victim in order "to keep 'un hot," the room being usually fireless, cold, more or less damp, whitewashed, and draughty. Under these circumstances a high mortality is not to be wondered at, for a complication of measles, toxæmia, obstinate constipation (sometimes putrid diarrhœa), broncho-pneumonia, or, worst still, capillary bronchitis, had to be combated—no easy task. How to warm the room was a knotty point to settle. Paraffin stoves did it well for some cases, but at great expense of oxygen and gave a bad odour—either being positively harmful to capillary bronchitis. The only other place for a fire was in the kitchen where logs eight feet long could be burnt on the hearth in the huge chimney built 200 years or more ago. To bring the child here would be impracticable, for the air drawn up the great chimney by combustion would freeze one side of the bed even if the other were roasted. To quote from your leading article, "no disease seems to admit of beneficial guidance and control more than measles," and conversely, as I have shown, rough-and-ready guidance is disastrous, for I can think of no case that died among those which I treated from the very beginning. Those cases which had been left long without skilful treatment either died within a few days or survived only after a severe hand-to-hand combat. There is no doubt that, unless in an exceptionally malignant form, scarlet fever is a much less formidable disease than that which is often regarded as "mere measles."

I am, Sirs, yours faithfully,

G. G. GIDLEY, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.

Cullompton, March 28th, 1898.

"VENESECTION IN APOPLEXY."

To the Editors of THE LANCET.

SIRS,—The case reported by Mr. Colin Campbell in THE LANCET of April 9th, 1898, is of great interest and one that should not remain imperfectly recorded. It would be well to know, if possible, the cause of the apoplexy—whether it was due to embolism (as the very conspicuous but temporary mitral systolic murmur would suggest) or to hæmorrhage; also, what was the probable location of the cerebral lesion. No mention is made, either, of any paralysis following the attack. If such particulars could be added while the case is still fresh in the memory of your readers it would make the story more complete and might help to determine the important point—viz., which cases of apoplexy are benefited by venesection and which are not.

I am, Sirs, yours faithfully,

F. LUCAS BENHAM, M.D., M.R.C.P. Lond.

Elizabeth-street, S.W., April 9th, 1898.

THE VACCINATION BILL.

To the Editors of THE LANCET.

SIRS,—As a public vaccinator I think we should make strenuous efforts to induce the Government to alter the time for compulsory vaccination from the age of twelve months to that of six months, to retain the public stations, and to make provision for medical attendance on children after vaccination whenever it is found necessary. You are aware that under the present system a very large number of children (over 156,000 in the year 1894) escape the vigilance of the vaccination officers and remain on their books as unaccounted for. With the proposed extension of time the chances are that that number would be increased threefold. It must also be remembered that the Royal Commissioners suggested that the period for primary vaccination should in future be the age of *six* months. My experience of over twenty years as a public vaccinator has taught me that, provided the children are in good health, the safest time to vaccinate them is at the age of from two to four months, and also that a very considerable proportion of parents do, in fact, prefer to have them done before they attain the age of three months. The reasons generally assigned for this early performance of the operation are (1) that the infants at that period do not suffer so much from the effects of the vaccination and (2) that there is much less danger of having the marks injured.

It has been stated that there is nothing in the new Bill indicating that it is intended to dispense with the public vaccination stations. But, Sirs, it must be inferred from the fact that domiciliary visits are to be made at a certain time by the public vaccinators. If my view is correct, then those parents who have hitherto preferred to have their children vaccinated at an early age will not have an opportunity of having them done except at their own expense. In case of an epidemic of small-pox breaking out in a populous town like Cardiff there would of necessity be a large number of children totally unprotected, and I cannot help saying that this is a very serious question and one which I hope will be duly considered by the sanitary authorities of all our large towns. Should the Government resolve to adhere to the time proposed in their Bill, then I hope some provision will be made for the inspection of children before they are allowed to enter any school whatever.

I am, Sirs, yours truly,

Cardiff, April 9th, 1898. T. GARRETT HORDER.

THE INCUBATION PERIOD OF SMALL-POX AND THE INFLUENCE OF VACCINATION ON THE SAME.

To the Editors of THE LANCET.

SIRS,—The letter of Mr. Collinson in your issue of April 9th in reference to "Some Points relating to Vaccination as Illustrated by Observations during the Present Epidemic in Middlesbrough" would seem to prove that the *incubation* period of small-pox is more than twelve or fourteen days; also that vaccination has no influence on the course of the disease even when practised in the incubation period. The cases (excepting one) quoted by Mr. Collinson show a period of something like fourteen days as the incubation period if we may assume that the patient received the infection from the first case that occurred in the house. This period, however, I am convinced is not sufficiently long to allow for quarantine purposes. During an experience of small-pox I had early in 1896 I soon found that fourteen days did not allow sufficient time for the occurrence of fresh cases, but found eighteen days to be apparently the period for some of the cases. One case, however, turned up after nineteen days. I then came to the conclusion that it was safer to have a period of twenty-one days, for after this period had elapsed no fresh case occurred. I find in Allbutt's System of Medicine that nineteen, twenty, or twenty-three days may be the period of incubation. Dr. Armstrong of Newcastle relates a case where twenty-one days was the incubation period.[1] With regard to vaccination running its usual course during the incubation period of small-pox there is no doubt. Whether it will do so after the eruption of small-pox has appeared I cannot say; but in THE LANCET of 1873[2] Mr. Furley of Edinburgh advocated the treatment of small-pox by vaccination and he seemed to think it modified the course of the disease. In my experience vaccination has no influence on the disease if performed in the incubation stage. I was unaware of this fact till the experience I had in 1896 or I had forgotten it. It goes to show that vaccinia and variola are two distinct diseases. I find in an old edition, 1873, of

[1] THE LANCET, April 10th, 1886, p. 715.
[2] THE LANCET, July 19th, 1873.

Practical Medicine, by Niemeyer, that he states on pp. 555 and 556: "During an epidemic (small-pox) persons who have been vaccinated but in whom the vaccination has not yet taken are attacked by small-pox and the two diseases run their course at the same time without modifying each other. These cases show that vaccination during the period of incubation of small-pox cannot cut short the disease and also that susceptibility to vaccination is not lost during the period of incubation." He goes on to say that vaccination and revaccination should be performed without delay as soon as small-pox is known in a neighbourhood.

I am, Sirs, yours faithfully,

WM. BERRY, F.R C S.Irel., D.P.H.F.P.S.Glasg.,
Medical Officer of Health of Wigan.

Wigan, April 11th, 1898.

"AN UNKNOWN LARVAL PARASITE."

To the Editors of THE LANCET.

SIRS,—Cases similar to the one so ably described under the above heading [1] by Dr. Frank Arnold are by no means rare on the West Coast of Lake Nyasa and in the country beyond. The worms are generally attributed by the natives to a fly of a mottled-brown colour, similar in shape to, but larger than, a big horse-fly, which is known by them as the "tshizeti." Some believe that the fly lays its eggs directly beneath the skin of the affected person; others that the eggs are deposited in large numbers upon blankets and other articles of clothing, and that the resultant maggots or "fusi" are able, while yet quite small, to penetrate the epidermis of the host.

I am, Sirs, yours faithfully,

Liverpool. STANLEY KELLETT SMITH.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Sudden Abandonment of Plague Operations in Bombay.—The New Measures.—Increase of Plague in the Punjab.—The Wounded Europeans.

THE work of the Plague Committee in Bombay has for all practical purposes suddenly ceased. Not that the plague is decreasing—rather the reverse; but a new policy has been adopted by the Government. This change was contemplated before the riots on March 9th, but a proclamation issued on March 15th states that general searching of houses for plague cases will be wholly given up. There will be no inspection of corpses and consequently no delay of funerals. The plague authorities will only take action against houses where undoubted cases of plague occur and there will be a relaxation of the pass systems, allowing free exit and ingress to *bonâ-fide* traders. This change is not only sudden but complete. It is stated that the operations of the Plague Committee were conducted in such a way as to create much discontent among, and hardships to, the native population, to very seriously hamper and injure the trade interests of Bombay, and to alienate all help from the natives themselves for the extermination of the disease. It is admitted that the results achieved have been far from satisfactory, but it is urged that a modification of the measures, which were based on general sanitary regulations, was all that was required. The new *régime* amounts to a distinct abdication of powers hitherto exercised by officers directly under Government to a collection of caste leaders with little or no sympathy in any sanitary measures for plague control, bearing little or no responsibility and undeterred by any consequences which may ensue. In truth, however, there are no recognised native leaders and no native committees have been formed. It is now left to the natives themselves to take their sick to their own native hospitals if they choose, to report houses where cases of plague have occurred, also if they choose, and to vacate their houses and go into the health camps of their own accord. With the general dislike to hospitals it is almost certain that the sick will be left to die in their own homes. No kind of isolation whatsoever will be practised. The "contacts" will be free to move about undisturbed and a small proportion of infected tenements only will come under notice for disinfection. There will, in short, be no measures whatever adopted to check the spread of the contagion. From previous experience it is impossible to place any reliance whatever upon the natives themselves for following up any of the sanitary measures hitherto adopted for their benefit. Moreover, they have no organisation, and their efforts, even if reliable, are entirely voluntary. While the number of plague cases reported daily has probably fallen very far short of the correct number it is reasonable to assume that a much larger proportion will now fail to be registered. The total mortality will alone give any indication of the ravages of the disease. Whether or not other considerations have determined the adoption of this new policy it is almost certain that the results from a sanitary point of view must be disastrous.

The Europeans injured in the recent riots are all progressing favourably. It is reported that a very much larger number of natives were killed and wounded than the figures officially published would seem to indicate. The plague is reported to be rapidly on the increase in the Punjab and many places in the Nizam's dominions have also been attacked. Preparations are being made to carry out Haffkine's prophylactic inoculations on a large scale in the latter territory. Among the 6000 Khojas of Bombay who have been inoculated only three cases of plague have occurred, which speaks highly for the protective value of this preparation. Some recent experiments with electrolysis of buboes have been attended with satisfactory results. Not only have the swellings rapidly diminished, but almost immediate improvement has been recognised in the general symptoms. From 10 to 15 milliampères is the strength used, which is kept up for ten minutes, and in most of the cases one operation has sufficed. This treatment is still being followed up and some results will be able to be published shortly.

The modified measures recently adopted by the Government appeared at first sight to have appeased popular feeling, but there are evidences of considerable discontent with even the very mild steps now taken. The following rules just promulgated contrast very strongly with the regular house-to-house visitation which was formerly carried out together with the compulsory segregation of all cases found into hospital, of many of the contacts to the observation camps, the emptying of crowded and insanitary houses, and the disinfection of plague-stricken premises on a large scale. It is now ordered that house-to-house visitation be carried on by the people themselves—i.e., by committees appointed from among them. Plague officials will search only those houses where cases or deaths have recently occurred or where there is a reasonable suspicion of a plague case.

No patient will be removed to a plague hospital unless an approved and fully qualified medical officer certifies it to be a plague case. If such a medical officer pronounces a case to be hopeless—i.e., only expected to live a few hours—such patient will not be removed to a hospital without the consent of the relatives. In the event of a case of plague occurring in the family of a well-known and well-to-do or respectable person the patient will be allowed to remain in the house and can be attended there by his own doctor and by one or two members of his family, provided the house is a detached one and the patient can be isolated and the family agree to remove themselves to one of the Plague Committee's health camps, or to dwell at a detached place where they can be placed under supervision. Where disinfection will suffice no destruction of property is now allowed. If, to diminish risk of infection, destruction of property is found to be necessary, compensation will, in the case of the poor, be paid on the spot. Infected houses will continue to be disinfected as heretofore. The owners or occupiers will be given the option of disinfecting their houses themselves to the satisfaction of the district plague officer. Contacts will continue to be removed as before.

The policy of depending upon the natives to notify cases of plague has not yet shown any improvement in the number detected. It is estimated that 600 cases of plague occur weekly which escape discovery by the staff of the Plague Committee. This is about half the mortality from plague. Large numbers die in their own homes, and large numbers are taken to the hospitals in the last stage of the disease and die there within a few hours. There is no reduction in the general mortality, and plague has now gradually spread to every quarter of the city in a very similar manner to what was observed last year. Fresh orders, still further in the

[1] THE LANCET, April 2nd, 1898, p. 960.

direction of leniency, have just been issued by the Government. They are as follows: 1. Persons are only to be compulsorily removed by order of a plague authority to a health or segregation camp when their house is known to be infected with plague and when they are unable to satisfy the plague authority that they will remain under observation in a sufficiently isolated and convenient place. 2. Voluntary removal to a health camp or other place of safety should be encouraged by all means possible. 3. If a plague case can be suitably treated and isolated in a house of sanitary situation, free from the danger of spreading infection, the patient may be allowed to remain, provided that the other occupants (save the immediate attendants) remove themselves elsewhere as above stated.

This week's mortality is the highest recorded during the present epidemic—the death-rate is at the high figure of 142·25 per 1000 per annum—2268 deaths having been registered. Four Europeans have died from plague. Relapsing fever is not quite so prevalent.

March 26th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Birmingham Medical Institute.

THE Medical Institute has never been a plant of vigorous growth. It has fulfilled in the abstract the indications for which it was founded in 1874; that is, it has provided a library and a place of meeting worthy of the profession. The library now contains more than 12,000 volumes; the reading-room is well supplied with periodicals and works of reference; the library hall affords a capital room for the meetings of societies; there are a lavatory and smoking-room, electric light, and most modern conveniences conducive to comfort. Yet the place does not thrive with all its advantages. The endowment is £6600, which, brings in an income of £238 a year, but the necessary annual expenditure exceeds over £490. At present there are only 166 subscribers of one guinea a year out of a large number of medical men in the town and district around. The report given at the annual meeting held on March 30th showed that the year ended with a deficit of £71 11*s.* 8*d.*, a sum which has since been wiped off by the generous contributions of a few leading members. Some suggestions have been made for selling the present site, building a new institute with the proceeds, and living within the income. It would be a matter of regret should such a proposal be carried out. The infusion of some enthusiasm and energy would probably form a better basis for future progress and save the ignominy of breaking up the existing institution.

The Athletic Institute.

The annual meeting was held on the evening of March 30th. The credit balance was stated to be £346 2*s.* 1*d.* The health lectures were popular and the cycling teaching had brought a distinct gain to the funds. The attendance at the classes was regular and the training had caused the majority of the members to attain a high standard of excellence. It was pointed out that the institute was the only one of the kind in the county outside London which was vested by the Education Department with authority to issue certificates of proficiency in teaching physical exercises in elementary schools and that it was growing in favour and importance. Open spaces and playing-grounds had done much to make the opportunities for recreation and exercise more within reach, full advantage having been taken of the various sports and games during the year.

Coroner's Duties.

During the month of March the city coroner has held 114 inquests. This is not the record number, but many of the inquiries have been protracted and important. It is enough to indicate the amount of work done by this official and to show that the office is one of great responsibility and involving much hard work.

April 11th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Rivers Committee and the Local Government Board.

AT the meeting of the Manchester City Council on April 6th a long discussion took place as to the present position of the corporation, the Mersey and Irwell Joint Committee and the Local Government Board in relation to the never-ending sewage difficulty. The last-named body insists on the purchase of land, apparently not caring much whether it is fit for the satisfactory treatment of sewage or not if only there are so many acres to so much population, and clings to its ancient dictum that irrigation is the proper way to purify sewage. The standard of purity required by the Joint Committee is difficult of attainment and the land at Davyhulme has been proved unsuitable for irrigation notwithstanding that in 1888 evidence was given by Dr. Frankland, Dr. Tidy, Mr. Estcourt, and others to prove that it was "loose, porous, and admirably adapted in every respect for the purpose of sewage filtration." Now, on the other hand, it is stated by Sir Bosdin Leech, the present chairman of the Rivers Committee, that it is unsuitable, that on the surface it became choked, while below the sand, instead of filtering, became a quicksand; and, further, the chemicals in the water were damaging to vegetation. Driven then to tank filtration this also failed to give a sufficiently pure effluent, so under the advice of Sir Henry Roscoe experimental filters were put down which gave satisfactory results but at an extravagant cost. The culvert scheme was next brought forward but rejected by the citizens. Now it is wished to give the biological system a careful trial on a large scale, but the Local Government Board blocks the way by insisting practically that whatever else they do land for irrigation shall be bought. Very shortly the corporation will be liable to a fine of £50 a day for not properly treating their sewage, so that there are difficulties all round. The discussion was long, many curious things were said, and if the truth must be told some who might have known better displayed unexpected ignorance. In the end, to the discredit of the council, members began to leave and there was a count out and the meeting was adjourned for a fortnight. It must be said, however, that such an occurrence is rare and that the council usually exhibits great patience during tedious discussions. The fortnight's adjournment may be profitably employed by some in obtaining clearer ideas and some additional knowledge, for one of the opponents of the bacterial scheme argued that it must fail as bacteria must have time for rest which was impossible as the flow of sewage is continuous. He advocated a good system of precipitation as the only one practicable for a place like Manchester and looked upon the other plan as "bacterial humbug." But he is really unjust to his own intelligence and that of the council. The chemist of the Rivers Committee, Mr. G. J. Fowler, has prepared a report on the experimental filters at Davyhulme which concludes as follows: "While it cannot be guaranteed that under no circumstances will a filtrate be obtained which is above the Joint Committee's numerical standard, yet with very few exceptions it has been shown that a filtrate which is incapable of undergoing putrefactive change can be constantly obtained from the cinder filter. With increased knowledge of the conditions of successful filtration of such a tank effluent as is produced in Manchester it is likely that even more satisfactory results, both as to quantity filtered and quality of the filtrate obtained, may be looked for in the future."

Manchester Literary and Philosophical Society.

An interesting ceremony took place at a special meeting of the Manchester Literary and Philosophical Society, held on March 29th, when the Wilde medal was presented to Sir Joseph Dalton Hooker. In his acknowledgment of "the great honour which the society had conferred upon him" Sir Joseph Hooker said that "Manchester held a place among his earliest botanical reminiscences." He was a collector of mosses in the first decade of the 80 years that had passed over him and was stimulated by a book with the title "Musci Britannici," by Edward Hobson of Manchester. He recalled the names of Nowell and Buxton, two of the band of working-men botanists who have for

generations served as a scientific leaven among their fellows in Manchester and South Lancashire, and said that when his friend Mr. Glover, an excellent botanist and entomologist, invited him to see his collection of insects and rare garden plants at Smedley-hill, "though this was sixty-five years ago he noticed that the latter suffered a good deal from the city smoke." But there was none to whose friendship and correspondence he looked back with greater pleasure than to that of the late Professor Williamson, who was a remarkable instance of the successful cultivation of natural history, and especially of the organisation of the fossil plants of the coal measures, while he was busily engaged in general practice. Sir Joseph Hooker "accepted the medal as a tribute to his father's memory as much as to his own exertions." The Dalton medal was then presented to Dr. Schunk, F.R.S., who is its first recipient, for the life-long services he had given for the advancement of science. Lastly, the Wilde premium of 15 guineas was presented to Mr. John Butterworth of Shaw, who has done excellent work, particularly in regard to the flora of the coal measures. He is one of the band of Lancashire working men imbued with the love of science for its own sake. In thanking the society he said he had worked for nearly 30 years with the late Professor Williamson. In his early days he had not the advantage of systematic instruction; it was "a case of the night school and solitary candle. He had pursued the study of geology purely for the love of it and had found great enjoyment among the flora of the coal measures." Will the teaching now given in our public, elementary, and other schools increase the proportion of these humbly born lovers of knowledge?

Seats for Shop Girls.

A well-attended meeting of the local branch of the National Union of Women Workers was held on March 29th at the Manchester Town-hall. In the absence of the Lord Mayor the chair was occupied by the Hon. Mrs. A. T. Lyttleton, president of the branch. The question of "seats in shops" was one of the subjects considered and a statement was circulated among the audience setting forth the evils and the cruelty of continuous standing, often resulting in serious injury to the women and girls employed in shops and restaurants. Dr. Sinclair moved a resolution strongly supporting "the Bill to amend the Law relating to Shops, and especially Clause 9, which is before the House of Commons this year." It was seconded by Dr. Wilkinson and both gentlemen spoke from the medical aspect on the evils of prolonged standing, advocating strongly more humane treatment as regards the provision of seats. Mrs. William Crossley said there were thousands who had to stand from 8.30 in the morning to 6.30 in the evening. She suggested a conference with the employers and said she had little doubt of a good result. A letter was read from one of the principal firms in Manchester saying they had for some years provided seats and expressed the wish that they should be made use of. Mrs. Lyttleton pointed out that the chief evil arose not in the shops frequented by the well-to-do but in those of a lower class, and that to deal with them legislation was necessary. The crusade in favour of seats in shops, with permission to use them, has been carried on for many years, but it would seem with little actual success. Legislation ought not to be necessary for the carrying out of so obviously humane a practice, but it seems to be. Who can say precisely where the fault lies? It probably should be pretty evenly distributed, but if the countless host of well-to-do women customers were in earnest and brought their influence to bear on the employers seats would be provided in the shops as rapidly as they could be fixed by the joiners.

April 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Glasgow University.

AT a meeting of the Senate on April 4th the commission from the Crown appointing Dr. John Glaister to the chair of Forensic Medicine was submitted and Dr. Glaister having been introduced to the Senate and having signed the declaration *de fideli* was admitted to office in the usual form. During the past week a number of students under the direction of Dr. Gemmill, lecturer on embryology, and Dr. Rankin, demonstrator of zoology, have taken advantage of the recess to prosecute the study of practical biology at the new marine institute at Millport. The excursion has proved in every way a great success. By dredging and netting an ample supply of material has been readily obtained and the facilities and equipment offered by the laboratory have given every satisfaction. This new departure in practical work for the university students has demonstrated the excellent opportunities offered by the Millport district and institute and there can be no doubt that an increasing recognition of these will promptly follow.

The Aerial Transmission of Enteric Fever.

A paper on this subject was read before the Glasgow Philosophical Society on April 6th by Dr. John Brownlee of the Belvidere Fever Hospital. The lecturer regarded it as proved that the enteric bacillus could live in arable and other soils and he described an experiment in which he proved the same possibility in regard to ordinary dust. He also gave details of an outbreak of enteric fever which occurred in one of the city hospitals. Some few cases of the fever had been admitted and when subsequently the drains were under repair a considerable number of cases developed in all parts of the hospital. Dr. Brownlee regarded these and other instances as proofs of the theory that the germ of the disease may be transmitted through the air and advocated the pursuit of sanitary measures based on this assumption.

April 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

A SPECIAL general meeting of the Irish Medical Association was held at the Royal College of Surgeons in Ireland on March 29th. The committee of council afterwards held a conference in order to consider communications received in reference to the Local Government Bill. The meeting adjourned until April 7th, when the Bill was considered in the interests of Poor-law medical officers. The Council has addressed a letter to the Chief Secretary for Ireland with particular reference to clause 58 and it is hoped that he will accede to the request made. Poor-law medical officers in Ireland were requested to take the necessary steps to obtain the assistance of their Parliamentary representative in support of certain amendments to the Bill. At the meeting of the council held on March 16th it was decided that an appeal should be made—on the advice of its law agent and the opinion of senior counsel—against the decision of the Court of Queen's Bench relative to the fee claimed by the medical officer of health of Midleton Union for evidence in a sanitary prosecution.

Dispensary Medical Officers' Substitutes.

The vexed question as to the payment of a dispensary medical man's substitute has recently been adjudicated upon in Limerick. Dr. Graham of that city required a substitute to act for him during a recent illness and he, with the sanction of the board of guardians, appointed another medical practitioner—Mr. Humphries—to act in his stead. At a meeting of the Dispensary Committee, held on March 30th and convened for the purpose of considering an application of Dr. Graham for a further extension of his sick leave, a letter was read from the Local Government Board suggesting that in future in appointments of this nature it would be wise for the committee in the interests of the sick poor to see their way to the selection of an officer who could devote his entire attention to the work. The committee recognised the wisdom of the suggestion and instead of re-appointing Mr. Humphries, who is a dispensary medical officer in large private practice, appointed to the temporary post a medical man free from public duties in the district.

The Feeling in Dublin in reference to the Army Medical Department.

The interest which is felt here in reference to the Army Medical Service has been increased rather than diminished by the strangely conflicting replies of the Royal Colleges of Physicians and Surgeons respectively to the request of the Director-General. The Council of the Royal College of Surgeons met on March 29th for the special purpose of considering the matter and after an exciting debate decided

to accept the suggestion and to nominate two surgeons for temporary service in the Army Medical Department in reliance on the pledge given by the Government that the newer reforms would be carried out. At a largely attended meeting of the President and Fellows of the Royal College of Physicians held on April 1st the following carefully considered resolution was unanimously adopted:—

Pending the issue of a warrant in accordance with the statement recently made in the House of Commons by Mr. Powell Williams, M.P., Financial Secretary to the War Office, as to prospective arrangements for improvements in the Army Medical Department, which arrangements, if carried out as indicated, would, it is believed, at once secure a competition by a sufficient number of high-class candidates to fill the vacancies that now exist in the service by competitive examination in the ordinary manner, the College is of opinion that, in the interests of its Licentiates and of the Army Medical Staff, it is not advisable that any recommendations for the temporary employment of civil surgeons for duty with Her Majesty's troops in the United Kingdom should be made by the President in accordance with the request made to him by the Director-General.

The College of Surgeons considered the somewhat vague statements as to the new warrant which emanated from Lord Lansdowne to constitute the beginning of a new era for the army surgeon and acted on that perfectly natural assumption. The other College decided on not moving until the document itself appears. The resolution of the latter—the College of Physicians—was quoted in full in the columns of the *Irish Times* of April 2nd and formed the subject of one of the numerous leading articles on the matter which have recently appeared in that journal. The general feeling in Dublin seems to be very much what is embodied in the leading article in THE LANCET of April 2nd—namely, that the Army Medical Staff and the profession are to be congratulated on the very successful issue of their controversy with the Government.

Decision of the Local Government Board with Reference to the Medical Officer of the Cashel Union Infirmary.

At the last meeting of the Cashel board of guardians held on April 7th a letter was read from the Local Government Board containing the decision of the board on the sworn inquiry held some weeks ago into the conduct of the medical officer of the workhouse in relation to trained nurses recently employed there. The letter criticised the action of the medical officer in very strong terms on the grounds, firstly, that he permitted the dispensary midwife, who was in attendance on a case of puerperal fever, to leave the workhouse and attend cases outside; secondly, when acute cases of typhus fever were admitted to the fever hospital he took no steps whatever to have the trained nurse who was in attendance on the puerperal case removed from the fever hospital although she herself called his attention to the matter, while he tacitly sanctioned her sleeping in the same room with the nurse in charge of the typhus fever case; and thirdly, the action of the medical officer in instigating the nurses to write a highly objectionable letter to the guardians was quite unjustifiable. The document goes on to say: "Under all the circumstances the Local Government Board have reluctantly come to the conclusion that the medical officer has by his conduct forfeited the confidence of the board of guardians and they (the Local Government Board) entertain serious doubts whether he should be permitted to retain his position in connexion with the workhouse." In conclusion the board suggest that on this point the guardians should convene a special meeting of themselves in order to consider the matter and intimate that in the event of their feeling justified in giving the medical officer an opportunity of retrieving his position they (the Local Government Board) will be prepared to consider the propriety of acceding to their wishes after the officer has apologised for his conduct and promised an amendment for the future. The friction and trouble which have existed between the guardians of the Cashel Union and their union medical officer have been the subject of local public interest for very many months—even years—and have occupied many columns of the local journals in the shape of letters and leading articles. Nobody seems to doubt the ability of the medical officer in question, but it is at the same time clear to everyone that he has failed to recognise the fact that he is, however able and independent, the salaried officer of the board of guardians whom he has taken pleasure in defying.

Visit of Professor Schäfer, F.R.S., to Belfast.

Dr. J. A. Lindsay, President of the Ulster Medical Society, invited the members of that society as well as several leading men of the medical profession in Ulster to a reception in the Museum, Belfast, on April 5th, to meet Professor Schäfer, F.R.S., of London, who has been spending a short holiday in Belfast. A very large number accepted Dr. Lindsay's hospitality and the entertainment was in every respect a success. Those present subsequently adjourned to the lecture-hall of the Museum, where Dr. Lindsay took the chair, and in very complimentary terms introduced Professor Schäfer, who gave an interesting address on the Causes of Glycosuria. He believed there were many causes of sugar appearing in the urine and he gave an interesting account of glycosuria caused in animals by a vegetable drug, phloridizin. The causes of glycosuria which he specially dwelt on were (1) the alimentary, (2) the nervous, (3) the renal, and (4) the pancreatic. His remarks on the kidney form were of great interest and he described certain experiments made by himself and an old Belfast student, Mr. Benjamin Moore, M.A. (who is now assistant Professor of Physiology at University College, London), to elucidate the question of pancreatic diabetes. The results are not yet completed. At the conclusion of his address Professor Schäfer was awarded a hearty vote of thanks on the motion of Dr. Redfern, seconded by Professor Cuming, M.D.

Belfast Board of Guardians.

As a result of the Poor-law elections in Belfast just declared the two lady candidates are elected and one of them is successful in two of the wards. This will necessitate another election and it is expected that another lady will come forward.

Belfast Corporation (Hospitals) Bill.

The Roman Catholic ratepayers and inhabitants of Belfast have deposited in the Private Bill Office of the House of Lords a petition asking to be heard by counsel in opposition to the Belfast Corporation (Hospitals) Bill when it is reached. The second reading in the House of Commons on April 4th was postponed until Tuesday, April 26th. The representatives of the Mater Infirmorum (the Roman Catholic) Hospital have issued in pamphlet form (27 pages) their claim, a copy of which has been sent to each Member of Parliament. They say that as the Royal Victoria Hospital has been granted a free site their hospital should be freed from ground-rent. Their ground-rent is £100 per annum and they suggest that the Belfast corporation should either pay this or provide a fund to be invested in trust for the purpose of producing the necessary annuity.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Sequel to the Laporte Case.

AN account has already been given in the columns of THE LANCET of the meeting of the Society of Legal Medicine when the expert witnesses in the Laporte case, who were so violently attacked by M. Varnier on account of their report, were honoured by the passing of a resolution declaring that the documents upon which M. Varnier founded his attack were inaccurate copies of the official documents. A controversy has since been raging in the medical press between M. Varnier and M. Socquet, one of the impugned experts. M. Varnier argues that the discrepancies between the version of the evidence on which he based the attack and the official copies were merely due to a copyist's error. At the meeting of the Society of Legal Medicine held on April 4th M. Pinard read a long memorandum in which he took upon himself the responsibility for M. Varnier's charges and attempted to sustain the theory, in the face of the remarkable declaration of M. Maygrier and the evidence offered by the latter at the last meeting of the society, that the perforations found at the post-mortem examination could have been spontaneous. He also argued that the resolution passed by the society at its last meeting was too general and implied that all the documents used by M. Varnier were incorrect, whereas there was only one which had any error in it. M. Socquet took up the discussion and in a moving speech complained that he had been most violently attacked as to his skill as an expert by M. Varnier and that he had been accused by him of having been the cause of the arrest of Dr. Laporte by having sent in to the examining magistrate a summary report of only

seven lines in length which had been discussed word by word but in fact had no real existence. He demanded from M. Pinard that he should give the name of the copyist by whose error M. Varnier was deceived. The society passed another resolution declaring for the second time that what M. Varnier had called the summary report of M. Socquet was not exact.

A Loan of 1,700,000 Francs.

The University of Paris, the reconstitution of which is of so recent a date, has just accomplished the most important act of its new life—that is to say, it has taken up a loan amounting in all to 1,700,000 francs. The law, in fact, which has reconstituted the universities has given to them a civil personality: they have their own budget and their own sources of income, which are definite and assured, and they are able to contract loans on the security of these sources of income. The 1,700,000 francs which the university has borrowed will be devoted to carrying out two schemes. The greater part of this sum will be devoted to the construction of buildings for the accommodation of first year students in medicine. Up to this time the schools for these students had been housed in the most defective manner in the Rue Rataud, close to the schools of physics and chemistry. The city of Paris, to which these latter buildings belong, has courteously lent them to the university, but the city wishes to realise its property, and, besides, the students are very badly housed in their present quarters. Therefore very much more suitable buildings will be erected in the Rue Cuvier. The other portion of the loan will be devoted to the keeping-up of a laboratory of natural history at Fontainebleau. Anyway, some resolution must be definitely come to, for both the work at Fontainebleau and that in the Rue Cuvier ought to be commenced during fine weather. At the last meeting of the council of the university M. Gréard said that the negotiations relative to this loan were far advanced and the contract would be submitted without delay for the ratification of the Minister of Public Instruction.

L'Assistance Publique.

The governing body of the Assistance Publique has just held its annual meeting. The retiring board, the members of which were M. Théophile Roussel (senator and president), M. Sabran, and Dr. Thulié (vice-presidents) were re-elected with acclamation. The council entered on the discussion of the first question on the orders of the day—namely, a project for the internal regulation of hospitals and infirmaries. At the third meeting, held under the presidency of M. Sabran, the vice-president, M. Henri Monod, Home Office representative on the Assistance Publique, laid before the board the reports upon which the Home Office wished to consult the board. The following questions were submitted: 1. Are there exceptional cases where hospital physicians and surgeons can be authorised to receive fees directly from hospital patients? This question was remitted to the second and third sections. 2. Is there any room for making in public lunatic asylums special wards for the observation of those who are getting better by means of trial discharge, so that a period shall elapse between the time of their admission and their regaining full liberty? This was referred to the fourth section. 3. What is the best way of organising the Assistance Publique in the case of young discharged prisoners so as to carry out Article 19 of the Decree of Aug. 12th, 1890? This was remitted to the first section. 4. Methods of organising public assistance for legitimate children under the care of mothers who are either widows or divorced or deserted. This was referred to the first section. At the sixth meeting the chief subject of discussion was a report of Inspector-General Napias on the providing of subordinate officials for the charitable establishments. Dr. Napias considered it would be well to ask the administrative committees of hospitals that they should make it necessary that their subordinate staff should have had some professional education. M. Henry Michel, who agreed entirely with Dr. Napias, said that the professional instruction of nurses of both sexes and the examinations which establish the competence of candidates should be very simple, very practical, and as little theoretical as possible. The meeting passed two resolutions, the second one of which, proposed by M. Hebrard de Villeneuve and backed by most of his colleagues, was couched in the following terms: "That this council considers that women ought to be called to take part in all committees charged with the duty of administering public charities."

The Antitoxic Action of Nervous Tissue and Various Inert Substances upon Strychnia.

M. Toinot and M. Georges Brouardel communicated to the meeting of the Hospitals Medical Society held on March 29th some observations of M. Widal and M. Nobécourt upon the Antitoxic Action of Pulped Nervous Tissue upon Morphia and Strychnia. If a mixture of one gramme of nerve substance and a mortal dose, or even twice a mortal dose, of sulphate of strychnia is injected into a guinea-pig M. Toinot and M. Brouardel found that the animals in question invariably lived. The observers made researches into the cause of this interesting fact and found that strychnia was really present in the mixture, that it had not lost its toxic properties, that dilution of the poison made no difference, and, finally, that guinea-pigs thus experimented on, if treated with a fatal dose of strychnia forty-eight hours afterwards, always died, showing that they were neither refractory nor immune. M. Toinot and M. Brouardel also tried the effect of fatal doses of strychnia mixed with various inert substances such as charcoal, talc, potato starch, and spinach, and they found that an admixture of these substances had the same preservative effect as nerve pulp if used in the same proportion and doses. Results were just the same whether the mixture was made twenty-four or forty-eight hours previously to the injection or immediately before. The explanation of these results apparently so mysterious is in reality very simple and is easily verified by a chemical experiment. Mixtures of carbon, talc, or nerve pulp with strychnia give a filtrate which is absolutely non-poisonous to guinea pigs and which, when tested, shows not the least trace of poison, which, however, can be extracted from the material left behind on the filter. It is obvious, then, that in an injection of this mixture the poison is so fixed and held that it cannot act as a whole but is only set at liberty very gradually, and the very slowness of this action prevents a mortal dose being set at liberty at one time in the organism. Chemists know well that a solution will give up to inert bodies in certain cases that which it holds in solution and organic pulps have the same inherent properties and play the same part as inert bodies, as is evident by these experiments. These facts show, moreover, that we must not be too hasty in ascribing antitoxic properties to animal tissues.

Obituary.

The death of Dr. Worms, member of the Academy of Medicine, is just announced. He has left behind him several important works upon gout, diabetes, and the disorders of nutrition. He held the post of chief medical officer to the Chemin de Fer du Nord.—Dr. W. Martin Dürr has just died in the Hôpital de la Pitié at the age of thirty-two years. He formerly held the appointments of resident medical officer to the hospitals and head of the clinic at the Faculty of Medicine, while at the time of his death he was histologist to that body, so that he seemed destined for a brilliant future. Some years ago he was put in charge at Brest and Manbeuge of the various organisations for prophylaxis against cholera. He died in the hospital in a state of utter destitution and the resident medical officers of that establishment have published a strong protest in the daily press because the director and the financial staff of the hospital have refused to give even a shroud for his burial, while in addition the Assistance Publique, which he had served for four years as resident medical officer, have refused to pay any part of the expenses of his funeral.

April 12th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Tragic Death of a distinguished Medico-Psychologist.

BY one of those explosions of homicidal mania so frequent in Latin countries Dr. G. B. Ermacora, joint editor with Dr. Finzi of the Milanese *Rivisti di Studi Psichici*, has lost his life at the early age of thirty-eight years. Dr. Ermacora had, it seems, incurred the enmity of his cousin, the engineer Signor Piva, nephew of the well-known general officer of that name, by his having become entitled by will to a considerable fortune on which young Piva had been counting as in great part his own. The doctor on a visit to Rovigo had called on his cousin and was in the act of holding out to him the right hand of conciliation when

the latter seized a revolver lying beside him and shot Dr. Ermacora dead. Immediately thereafter Signor Piva committed suicide by blowing out his brains with a loaded carbine. The consternation and grief of the two families well known in the Alta Italia—Piva and Ermacora—may be imagined. "Among the cultivators of the physio-psychological sciences," writes a medical friend, "Dr. Ermacora excelled in acuteness of thinking power and in the austere scientific rigour of his investigation. He had recently brought to a close a series of studies on 'Telepathy' and 'Premonition,' which, in published form, attracted much attention in France, in Germany, and in Austria-Hungary." He had also an unusual command of the literature of his subject and was often appealed to by colleagues and fellow-students for the best sources of information on medico-psychological themes. He had latterly been giving much attention to the English school of "Psychical Research" and was himself the author in his *Rivista* of "annotations" on the subject which (says the writer above quoted) "will remain a model of scientific integrity and unbiased judgment." The tragic incident occurred on March 23rd.

"*Pro Montibus.*"

Following up the crusade "Pro Silvis" started by the late Professor Cantani of Naples, the Turin school has initiated a movement equally devoted to arresting the destruction of forests and to the promotion of re-planting. Under the title "Pro Montibus" a company of nature-students and medical men, most of them members of the Alpine Club, and now numbering 300, held their first meeting in the Subalpine Capital on March 26th, and set forth their programme for the protection of plants, the re-afforesting of the denuded hillsides, the regulation of the water-courses and the rehabilitation of the flood-visited tracts of upper Italy. The movement deserves all the success provisionally assured by the scientific and philanthropic distinction of its president, the senator, Count Luigi Sormani, the vice-presidents, Dr. F. Vallino and Count Cibrario, and its general secretary, Dr. L. G. Bonelli.

"*A Lurid Industry.*"

Poverty is a bad counsellor, said the Anarchist Acciarito when, just a year ago,[1] he attempted King Humbert's life; and the remark holds true in other directions than those affected by the self-styled tyrannicide or the amateur saviour of society. It is constantly suggesting and practising devices for the rehabilitation of the individual at the expense of the public and for a little private gain compromising the welfare of the community. Italy, as an exceptionally poor country, abounds in such devices, the latest of which, reported from Naples, has acquired the proportions of what a contemporary stigmatises as "una lurida industria." It is neither more nor less than this—the wholesale purchase by ragmen of the wadding or charpie used for surgical dressings in hospital and the sale of the commodity (after superficial washing) to tailors and upholsterers for the lining of mantles or overcoats and for the padding of sofas and easy-chairs. The "industry" had for some time been in full operation when Dr. Vincenzo Gauthier (professor of materia medica and therapeutics in Naples University and sanitary assessor, I believe, to the municipal authorities) was apprised of its existence and, as the result of investigations conducted by his officers, discovered and identified its chief promoters. These parties have been denounced to the "autorità giudiziaria" and will shortly be placed on their defence by the Public Prosecutor in terms of Article 320 of the Codice Penale. Meanwhile the Ufficio d'Igiene has established a vigilance service, relieved day and night, at the various hospitals and ambulances to collect and destroy by burning all the dressings and "avanzi di medicature" (medico-chirurgical appliances which have served their purpose), the great sanitary furnace at Pasconcello being the immediate destination of such refuse. Professor Gauthier's intervention comes not an hour too early. Not only wearing apparel and household furniture must have been made positively dangerous by the disgusting industry which he has just suppressed, but the fittings of cabs and railway carriages, into which padding enters so largely, would be not less open to the same sanitary objection. Thirty-six years ago THE LANCET'S commission on certain evils of railway travelling from the medical point of view dwelt emphatically on the effects of the exhalation from the woollen-stuffed seats of first- and second-class compartments when closed windows and crowded occupancy sent up the temperature. The headache and pallor and general discomfort so often complained of after a day or night's travelling under these circumstances were thus accounted for. But the "lurida industria" referred to imparts elements of mischief yet more serious. Infective diseases may become readily transmissible from the imperfectly purified or sterilised dressings employed for cab seats or railway cushions—all the more in a country where the inmates of first-class compartments have yet to be warned against "spitting outside the pocket-handkerchief," and where the standard of personal cleanliness is still at the level indicated by that tentative and perfunctorily respected "bye-law."

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Typhoid Fever in Victoria.

TYPHOID fever is still increasing in prevalence in Victoria. For the fortnight ending Feb. 19th the number of cases reported was: for the whole colony 427, with 43 deaths; for the metropolitan area 174 cases, with 15 deaths. For the corresponding period of 1897 the figures were: for the whole colony 220 cases, with 13 deaths; for the metropolitan area 108 cases, with 7 deaths. In some districts the disease is a perfect scourge. At a little country village named Lexton, with a population of about 140 all told, 44 cases of typhoid fever have occurred in six weeks. In this, as in most of the other instances, the water-supply appears to be the source of infection, the arrangement for the disposal of excreta and for the supply of drinking-water being as primitive and as insanitary as possible. In the metropolitan area, also, the infection is ascribed to pollution of the water-supply through the fire plugs when the pressure is low. The summer has been unique in respect of long continuance of excessive heat and drought, favouring contamination of water. The Board of Health have issued circulars for the information of the public pointing out how the water-supply became contaminated and urging all householders to boil all their drinking water and effectually filter it. The circular also deals with contamination of milk and the precautions to be taken to prevent it.

Infantile Mortality and the Milk-Supply in Melbourne.

Not only has typhoid fever been so exceedingly prevalent but the infantile mortality of the metropolitan area has gone up by leaps and bounds this summer and appears to be unquestionably due to the microbic developments in the milk which occur in the hot weather. In 1897 the Government passed a Factories and Shops Act which provided *inter alia* that in all trades the employés must be given a half-holiday once a week. The effect of giving the milkmen a half-holiday on Wednesdays is that people only get one delivery of milk early in the morning to last till the next morning and in the hot weather it will not keep. The increase in the cases of diarrhœa at the Children's Hospital on the days following the half-holiday has been most striking. When the Bill was before Parliament one of the honorary medical officers of the Children's Hospital wrote to the press prophesying what the result of the half-holiday for milkmen would be in causing infantile disease and his prediction has been completely verified.

Retirement of Dr. Manning.

As previously mentioned Dr. Norton Manning has resigned the position of Inspector-General of Insane for New South Wales. Before he retired the officers and staffs of the various asylums presented him with a very handsome address. It was illustrated with views of the various asylums and expressed the advantages the staff had enjoyed under his control, the efficiency to which the department had been raised during his long term of office and the deep regard, affection, and esteem in which he was held. Dr. Manning was also entertained at dinner by the medical profession of New South Wales. In replying to his health the guest of the evening referred to the changes which had taken place in the asylums of the colony during the thirty years

he had been connected with them. When he first took charge the buildings were prisons, the overcrowding was alarming, and the medical staff was inadequate—three medical officers for over 1000 patients in two asylums; now a competent staff of twelve has charge of nearly 4000 patients in five large, well-equipped and suitable hospitals. Dr. Manning attributed the success that has attended his work mainly to three causes—(1) that the Government allowed him to nominate and select all the members of the staff; (2) the energy, loyalty, and self-sacrifice of the members of the staff from medical officer to charge attendants; and (3) the generous help and appreciation of the medical profession. Looking to the future Dr. Manning said there was plenty of work for his successor in promoting asylums for the inebriate and for the more scientific study of insanity, especially by modern pathological methods. Dr. Eric Sinclair, superintendent of the Gladesville Asylum, has been appointed Inspector-General of the Insane in place of Dr. Manning.

The Sydney Hospital.

At a meeting of the board of directors of the Sydney Hospital on Feb. 1st Mr. Foreman called attention to the abuse of the charity and said that patients were admitted who had no right to the institution. He moved that a subcommittee be appointed to inquire into the subject. Some discussion followed pointing out the difficulties and the motion was lost. On Feb. 23rd the annual meeting of the hospital was held, his Excellency the Governor presiding. Previously to the meeting his Excellency formally opened the new pathological and bacteriological department attached to the hospital. The buildings and appliances are most complete and modern. The total cost was £3000, defrayed by a special Government grant. According to the annual report there were in the hospital on Dec. 31st, 1896, 271 patients and the admissions in 1897 were 3819. In the year those discharged cured numbered 2055; relieved, 1138; unrelieved, 266; died, 345; remaining Dec. 31st, 1897, 286; percentage of mortality on admissions, 11·8; average number of admissions per week, 73·4; largest number admitted in one week, 91; smallest ditto, 56; average number of beds occupied, 291; largest ditto, 314; smallest ditto, 268; average duration of stay in days, 24·3; number of accident and urgent cases admitted without recommendations, 1324; number of cases admitted on Government orders, 1341; number of cases admitted on subscribers' orders, 321; number of cases admitted who contributed to their maintenance, 833. Of the 345 deaths 73 died within twenty-four hours of admission. Of the deaths among medical cases 36 died from phthisis, 31 from other lung diseases, 8 from typhoid fever, and 24 from cardiac disease. Of the deaths among surgical cases 40 died from injuries and the remainder were due to diseases apart from accident. The attendances in the casualty department were 23,286; in the medical department, 22,033; in the surgical department, 12,569; in the eye department, 7040; in the ear, nose, and throat department, 5229; diseases peculiar to women, 6619; diseases of the skin department, 2897; and in the dental department, 3723. The operations performed during the year numbered 1954. The average cost per bed for 1897, including the expenditure of the Moorcliff branch, was £61 15*s.* 10*d.* The income for the year was £22,808 1*s.* 3*d.*, towards which the Government contributed £15,261 18*s.* 6*d.*—viz., £5398 16*s.* 8*d.* as subsidy on the £ for £ principle, £8813 1*s.* 10*d.* for the maintenance of pauper patients, £700 as subsidy for the Regent-street Dispensary, and £350 for rent of Moorcliff Branch Hospital. The attendance of out-patients had fallen by nearly 20 per cent. since 1895, when they numbered 123,000, and last year only 83,000.

The Medical Defence Association of Victoria.

The annual meeting of the Medical Defence Association of Victoria, Limited, was held on Feb. 24th. The report showed that a great deal of work had been done by the Council during the past year. No action at law had been defended, but assistance had been given in one case where the cause of action arose before the defendant in the case joined the association. A scale of fees had been drawn up and adopted as the recognised standard for the colony. The relations of the profession to friendly societies had been considered and in one case some concessions to medical officers were obtained. As a result of the action of the Council the fees paid for reporting infectious diseases to the Board of Health will probably be raised. The membership of the association had increased from 89 to 196. The association had a credit balance of £106. Dr. James Jamieson and Mr. Hall Owen were re-elected and Dr. P. B. Bennie was elected to the Council. The office-bearers were all re-elected.

Case of Hydatid of the Brain.

In the *Australasian Medical Gazette* for February is recorded a case of hydatid of the brain successfully operated on by Mr. O'Hara at the Alfred Hospital, Melbourne. The patient, aged thirty-six years, was admitted with aphasia and loss of power in the right arm, leg, and face. Illness began six months previously with twitching of the tongue and arm and epileptic fits. The fits lasted four months and then ceased. There was no optic neuritis at first, but this subsequently developed while under observation. The patient was trephined over the lower part of the Rolandic area. A needle drew off clear fluid. A cavity of the size of a bantam's egg was incised and drained. The evening after operation the patient had an epileptic fit. The tube was withdrawn. The wound healed and some improvement has occurred in the motion of the arm.

Case of Congenital Diaphragmatic Hernia diagnosed during Life.

At the February meeting of the Medical Society of Victoria Dr. Jeffreys Wood read notes of a case of congenital diaphragmatic hernia. The patient was aged fourteen months. The temperature at night was 97·6° F. and in the morning 95°. The pulse was 114 and the respirations were 48; the heart's apex was below the right nipple in the fourth right intercostal space. The percussion was dull on the left side of the chest and vesicular murmur was absent; posteriorly on the left side interstitial gurgling could be heard at times. When the child was inverted the lower part of the left chest became tympanitic and the note on percussion varied between tympanitic and dull, with variations in positions at different times. In consequence of the development of vomiting, constipation, and collapse it was thought that some strangulation had possibly occurred and abdominal section was performed. All the intestines were found in the left chest, but were not strangulated. The child died. There was a semi-circular deficiency in the posterior part of the left leaflet of the diaphragm 2 in. long. The spleen was in the left pleural cavity; the left lung was completely undeveloped. The peritoneum was continuous with the pleura round the opening. Death was probably due to ptomaine poisoning from impure milk.

March 2nd.

Obituary.

WILLIAM GROSVENOR, L.R.C.S., L.R.C.P. EDIN.

MR. W. GROSVENOR, of Churchdown, Gloucestershire, died suddenly from syncope on March 29th. Mr. Grosvenor was educated at Edinburgh University and also studied at Paris, taking the qualifications of L.R.C.S., L.M. Edin., in 1857, and L.R.C.P. Edin. three years later. Previously to going to Churchdown he had practised for twenty-five years in London. Mr. Grosvenor, who was in his sixty-first year at the time of his death, was held in high esteem in the neighbourhood. He leaves four sons—two of them are members of the medical profession—and three daughters. The funeral took place at Kensal-green on April 1st.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Rudolf Schneider, Extraordinary Professor of Surgery in the University of Königsberg.—Dr. S. Stricker, Professor of General and Experimental Pathology in the University of Vienna.

THE *Maryland Medical Journal* of March 26th states that the Cuvier Prize of the Paris Academy of Sciences, 1500 francs (£60) in value, has been awarded to Professor Marsh of Yale University. This prize is awarded every three years for the most noteworthy work published during that period on geology or zoology.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WEDNESDAY, APRIL 6TH.

THE first day's proceedings of the special session of the General Council of Medical Education and Registration were reported in THE LANCET of last week, and we now report the proceedings of the second and final meeting of the session.

The late Sir Richard Quain.

The President (Sir William Turner) submitted to the Council the following minute with regard to the late Sir Richard Quain, viz.:—

That the Council convey to the family of their late President an expression of sincere sympathy and personal sorrow at the great loss which they have sustained by his decease. Appointed for five years as a Crown Representative on Nov. 17th, 1863, Sir Richard Quain was re-appointed by successive Governments for the same period of time on six successive occasions. In 1864 he was elected by the Council as one of its treasurers and held that office uninterruptedly for twenty-seven years or until his election as President in 1891. Throughout his long and unbroken membership of the Council he was conspicuous for the zeal and devotion with which he applied himself to its affairs, no less than for the sagacity and moderation with which he took part in, and ultimately guided its debates. As treasurer he was a watchful guardian of its financial position and interests and as member or chairman of successive committees he was largely concerned in the preparation of all the issues of the British Pharmacopœia and in securing for that work the position which it has deservedly attained. In every capacity he endeared himself to his colleagues by a courtesy and geniality which never failed, by an equanimity which no differences of opinion could disturb, by a dignity and graciousness befitting the holder of a representative office in a great and learned profession, and by a warmth and kindliness of heart which were never for a moment obscured. The Council has not only to offer to his family an expression of the sorrow of the entire body, but also of its sense of the personal loss which each member has individually sustained by the death of so worthy and so beloved a colleague, and of so able and so excellent a president.

The minute was approved by the Council and it was agreed that a copy of it should be sent to Miss Quain.

The Midwives Question.

The Council then went into committee on this question and resumed the debate on the motion of Dr. Glover and Dr. Atthill—

That the term "midwife" shall be defined as meaning a woman who is registered under this Act and undertakes to attend only cases of natural labour.

Dr. MACALISTER said that this was the first time that they had admitted the word "registered" into their resolutions. He could not help thinking that much of the agitation which had taken place upon this question had arisen from the adoption of the word and of the ideas that it usually connoted. Registration had been adopted in the case of the medical practitioner and in that of the dental practitioner and it was thought that if midwives were registered they would become an inferior order of medical practitioner and would in some way ally themselves to the medical or dental professions now registered and assume a position which many medical men at least thought they were not entitled to assume. There was a suggestion made by Sir William Gairdner which might do a great deal to turn the force of this objection; he suggested that midwives should be licensed. He should therefore like in speaking against the proposal in its present form to speak against the introduction of the word "registered" and to suggest that in anything they did they should substitute "licensed." It might seem only a change of words, but in fact it was something very much more than a change of words. He would move as an amendment:—

That the term "midwife" shall be defined as meaning a woman who undertakes for gain to attend cases of natural labour and who is not registered under the Medical Acts.

While moving this amendment he wished to express the opinion that it was not for this Council to attempt to draft in detail the clauses of a Bill but rather to lay down certain general propositions.

Dr. LEECH seconded the amendment.

Dr. ATTHILL said that the suggestion about licensing was in entire accordance with his views. He had all along held that the word "registered" should not be applied to women who were not fully qualified practitioners.

Dr. GLOVER said that he had no hesitation in accepting the amendment, though he did not think there was much in it. He thought that whether these women were registered or licensed they would have the same authority to do what they had got to do. They spoke of a licentiate of the Royal College of Surgeons or the Royal College of Physicians or the Apothecaries' Hall. But to save time he agreed at once to the amendment. He wished to take this opportunity of saying that he thought it very important that at this meeting they should come to a decision of a final character upon this question. He wished to tell the Council that the subject had been considered by the Council in the following years: 1872, 1877, 1878, 1879, 1882, 1884, 1889, 1890, 1894, 1895, 1897, and 1898. This was a very grave matter, and in the form in which it was presented to them now and the speciality of this meeting made their deliberations peculiarly responsible and open to public criticism. He thought that every member would agree in thinking that whether they shut the subject up altogether or whether they agreed to some form of recognition of midwives they should at any rate give a final report, which would render it unnecessary and unreasonable for them to be asked to discuss it again. He estimated that the mere money loss to which the Council had been subjected by this subject had amounted to between £1500 and £2000, and therefore it was high time that they closed the matter by coming to some very definite propositions with regard to it.

The motion of Dr. Glover and Dr. Atthill was then with drawn and the amendment of Dr. MacAlister and Dr. Leech became the substantive motion.

Dr. MCVAIL pointed out that in its present form the motion excluded the unqualified assistant, and he suggested that instead of "woman" they should use the word "person." There could be no doubt that if legislation took place and the unqualified assistant were excluded there would soon be an agitation for his inclusion.

Mr. BROWN expressed approval of this view of the case, though he said he had no wish to press an amendment.

The motion as proposed by Dr. MACALISTER was then put and adopted.

Dr. MACALISTER said he had a plan to suggest which he thought would be better than going further into the details of the Bill and the committee's report, and that was to send up to the Lord President of the Council their views as to the general principles which ought to guide any legislation in regard to midwives. With this object he had drawn up a series of resolutions and these he would submit one by one to the Council for their consideration.

The Council decided to adopt this method of procedure.

Dr. MACALISTER moved:—

That the Council adheres to its previous resolutions that it is desirable that measures should be taken to protect lying-in women of the poorer classes from the grave risks which they now incur from the unregulated practice of midwives, many of whom are ignorant and unskilled and most of whom pursue their calling without due medical supervision.

Dr. LEECH seconded this resolution.

Dr. GLOVER said that he could not very well object to it because it was esentially the report of the committee in another form.

Mr. HORSLEY concurred in what Dr. Glover had said, and pointed out that all the propositions which Dr. MacAlister was going to put forward would be found in the report of the committee. He would like to know whether the general description of the Bill, the narration of the facts, would be put before the President of the Privy Council.

Dr. MACALISTER said he did not think this would be necessary, because the President knew perfectly well what the Bill was.

Mr. HORSLEY said the President was no doubt aware of what the Bill contained but he might not be aware of the omissions, and in this narrative the committee pointed out the omissions.

The resolution was then agreed to.

Dr. MACALISTER moved and Dr. LEECH seconded the following resolution, which was adopted by the Council:—

That to this end it is desirable that every woman who not being a registered medical practitioner engages for gain in the practice of midwifery should be subjected to legal regulation and control.

Dr. MACALISTER, seconded by Dr. LEECH, next moved:—

That any measure which proposes merely to protect the title of midwife, however defined, and does not make illegal and penal the unlicensed practice of midwifery for gain cannot be regarded as satisfactory in the interests of the public health.

Dr. GLOVER said he desired to support this proposition. It was the strong feeling of the committee that without this provision they could not recommend the adoption of any Bill. It was said that Parliament was reluctant to restrict personal liberty and was against the establishment of a monopoly, but this was not a question of monopoly, it was a question of mortality; it was a case of the death of 1000 women and perhaps 1500 children every year. It was not a question of monopoly, it was a question of the earnestness of Parliament in wishing to stop this mortality.

Mr. HORSLEY thought the words "cannot be regarded as satisfactory" were hardly strong enough.

It was agreed to substitute "cannot be regarded as offering a satisfactory safeguard," and thus amended the resolution was adopted.

It was next agreed:—

That some central body should be established by Parliament whose functions should include the framing of the conditions under which midwives may be licensed and the regulations under which alone they should be allowed to practise.

Dr. MACALISTER, seconded by Dr. LEECH, then moved:—

That the conditions and regulations so framed should be subject to the approval of the General Medical Council, and if and when so approved should be issued under the authority of the State department which is concerned with the public health.

Dr. MACALISTER said that he thought the Council should have a final voice in the matter and that the conditions and regulations should be uniform throughout the country.

Dr. GLOVER called attention to the following paragraph in the report of the committee, viz.,

That since the duties proposed to be cast under the Bill on the General Medical Council could not be carried out unless a considerable portion of each sitting of the Council were devoted to that purpose, which would involve a large increase of expense, and since the funds of the Council consist solely of fees paid by medical practitioners for admission to the Medical Register in Scotland and Ireland, as well as in England and Wales, such additional duties ought not to be imposed upon the Council unless a grant be made by the Treasury to meet the expenses involved.

He thought that some stipulation of this kind should be inserted.

Dr. MACALISTER said he was afraid that the paragraph read by Dr. Glover was rather too strong if the Council had only to approve rules framed by somebody else.

The Council agreed to the resolution moved by Dr. MacAlister with this addition, moved by Dr. GLOVER and seconded by Mr. HORSLEY:—

And that provision should be made by Parliament for reimbursing the Council for any expenditure which it may have to incur in performing the duty hereinbefore referred to.

The next resolution was adopted in this form:—

That every woman before beginning to practise as a midwife in any district should be required to take out a licence to be granted by the local sanitary authority of the district, issued under the prescribed conditions and regulations, and that such licences should be subject to annual renewal and should be revocable at any time in case the holder is proved to have infringed any of the prescribed regulations.

The next two resolutions adopted were to this effect:—

That any unlicensed woman, whether calling herself midwife or not, who not being registered under the Medical Acts practises as a midwife for gain in any district, should be made liable to a substantial penalty. And, That the conditions under which licences are granted should include the production of satisfactory evidence of character and of training and experience in the conduct of natural labour and the after-care of lying-in women and new-born infants.

Dr. MACALISTER moved and Dr. LEECH seconded:—

That the regulations under which licensed women are required to practice should include provisions securing that the midwife shall immediately seek qualified medical assistance in every case which presents symptoms of difficulty, abnormality, danger, or disease on the part of the mother or of the new-born infant.

Dr. GLOVER said he thought it should be the duty of the local sanitary authority to appoint medical practitioners to whom midwives might refer.

Dr. MACALISTER submitted that if the midwife found a person in danger she should be free to send for the nearest medical practitioner whom she could get.

Dr. GLOVER read to the Council the following recommendation of the committee:—

That it shall be the duty of the local sanitary authority of every district to appoint such registered medical practitioners as are willing to be so appointed, to whom midwives shall be required to apply for assistance and advice in all cases other than cases of natural labour, and under all circumstances which may be laid down by the Midwives' Board as calling for medical intervention. The local authority shall pay to every registered medical practitioner so consulted a sum of not less than one guinea and not more than two guineas; provided always that when the patient is able to pay for such medical services the local sanitary authority shall recover the fees for the same from the patient or other responsible person by ordinary process of law.

The committee, he said, attached great importance to this paragraph. The only condition under which they could consent to this new class of recognised persons was that they should be obliged to put themselves in communication with the medical profession on the occurrence of the slightest irregularity. Every medical man would not be willing to be at the beck and call of a midwife and therefore it should be laid down distinctly that it was the duty of the local sanitary authority to appoint one or more practitioners in their district.

Dr. MACALISTER said that Dr. Glover was proposing some local machinery which had nothing to do with the midwife.

Dr. GLOVER replied that the midwife must know where to look to for assistance.

The Council decided in the meantime to accept the resolution as moved by Dr. MacAlister.

Dr. GLOVER then moved:—

That it be stipulated in the Bill that it should be the duty of the local sanitary authority of every district to appoint such registered medical practitioners as are willing to be so appointed, to whom midwives shall be required to apply for assistance.

Mr. HORSLEY seconded this proposition.

Sir WILLIAM THOMSON asked whether the midwife would be able to apply for assistance to a person who was not appointed by the local sanitary authority.

Dr. GLOVER replied that this difficulty could be met. What he wished to make clear was that the midwife was not only required to apply for assistance but that her position was facilitated by a permanent appointment.

Dr. LEECH, seconded by Dr. ATTHILL, moved as an amendment:—

That it should be the duty of the local sanitary authority of every district to appoint such registered practitioners who are willing to be appointed to give assistance in those cases of labour as may necessitate by the regulation of the central board the attendance of a registered medical practitioner.

Mr. BROWN took the view that no particular person should be appointed, but that the midwife should be free to call in the medical man who was easiest reached. He thought they should make the assistance as wide and general as possible.

Dr. BRUCE asked whether it was necessary to go into all this detail. He had had considerable experience of midwifery and midwives and he had never heard of a medical man who showed any hesitation in giving assistance in a case of difficulty. He did not think that a regulation of this kind was necessary.

Dr. MACALISTER took the same view. He felt quite sure, he said, that in practice there would be no difficulty in getting the assistance of the nearest medical man.

Mr. CARTER reminded the Council that the midwife could not leave her patient and must therefore instruct someone to go for assistance. For himself he had never heard of there being any difficulty in obtaining a medical man when he was wanted.

Dr. GLOVER said that what he had in view was not the payment of medical men but the protection of lying-in women, and he would remind the Council that there were many public provisions for emergencies. There were police provisions by which a policeman was entitled to call in anyone he could get hold of to assist him, and in other countries—in France, for instance—there were emergency practitioners. Therefore he proposed that the Council should make it clear that this duty should be faced by the local sanitary authority.

After some further discussion Dr. Leech's amendment was withdrawn and the motion of Dr. Glover was defeated by a large majority.

Dr. MACALISTER said that the last resolution he had to propose was this:—

That in so far as the Bill submitted to the Council is not in accordance with the general principles above laid down the Council do not regard it as offering an adequate solution of the question under consideration and would earnestly deprecate its passing into law in its present orm.

Dr. LEECH seconded the resolution, which was also adopted.

The business in committee having been concluded the Council, on the motion of Dr. MACALISTER, seconded by Mr. BRYANT, resumed.

Dr. MACALISTER then brought up the report of the proceedings in committee on that day and the day preceding. He moved that that part of the report beginning with the words, "that the answer of the Council be to the following effect," be adopted.

Mr. BROWN seconded. He thought they had followed the more commendable course in proceeding as they had done that day. It was obvious that within the time at their command it would have been absurd to have attempted to draft a Bill which would meet the case, but they had passed this series of general resolutions and he was sure it would meet with the approval of the profession outside the Council. There was no objection to women being licensed to practise as midwives. They did not wish to throw obstacles in their way, but they did wish to prevent ignorant people from practising and the point was met very well by the resolutions.

In answer to Dr. MCVAIL Dr. MACALISTER admitted that in 1895 the Council had approved of a Midwives Registration Bill, but the resolution to that effect was not brought in in the present instance. Only those previous resolutions affirming the desirability of measures being taken to protect lying-in women of the poorer classes were included.

Dr. MCVAIL doubted if the registration resolution was not included. They should make it plain to the Privy Council if it was not included. He rather thought that the first of Dr. MacAlister's series was a resolution in which the word "registration" was used.

The PRESIDENT said that the resolution in question did not refer to registration but to the protection of lying-in women.

Dr. MCVAIL: Yes: but it does not stop there. It asks us to approve of what has formerly been passed.

The PRESIDENT: I think the Council is quite safeguarded in that.

Dr. GLOVER: We are quite in the lines of our fundamental intentions and whether it is a question as between licensing and registration we are acting quite consistently.

Dr. MCVAIL wished to make a remark or two. The Council, he said, knew that he had withdrawn his proposed resolution declaring that the Bill should not be passed by Parliament because the public safety required that any person who was to be recognised by law as a practitioner in midwifery should have a knowledge of midwifery, medicine, and surgery not less that was required for admission to the medical registration at present open to men and women equally. It was perfectly clear from the manner in which the Council had received the resolutions so ably proposed by Dr. MacAlister that afternoon that the Council had decided to send these resolutions to the Privy Council as their answer to the Lord President's request for an opinion on the Bill, but he thought it might be said that the resolutions were not the findings of the Council's committee on the Midwives Bill. There was nobody in that room who did not know that Dr. MacAlister had entirely overthrown the report of the Council's committee on the Bill. The series of resolutions proposed in committee of Council was quite a new thing. So far as he was personally concerned it did not meet his view in essence, but he would not stand in the way of its transmission to the Privy Council as the answer of the General Medical Council. It was quite true that it asked that women should be licensed annually, but it was still open for the Government and for Parliament to take the half of the recommendation and while resolving to create a new legal body of practitioners to determine at the same time that it was not necessary that they should be licensed. Parliament might say, "We shall not license them annually; we object to that." And he was quite certain of this, that when the decision of the General Medical Council reached the House of Commons the people who were promoting the Bill of which Mr. Balfour had charge would strenuously object to this licensing system, for it left a door open to all kinds of allegations being made against a licence-holder and, moreover, it was unfair to these women, who might be out at work, who were poor, or were ill, that unless they personally applied for license they should lose it or, in the case of new applicants, would not get it. In saying this he was only wishing to show what might be the possible action of Parliament. After the action taken by the Council the Bill concerning midwives would no longer be a Bill for the registration, but a Bill for the licensing, of midwives. The practically unanimous manner in which the resolutions were supported showed the very decided opinion of the Council in favour of licensing as against registration, and he thought that one effect of that would be that there would be no Midwives Act passed by Parliament this year and that they would again have an opportunity of saying whether they were parties to the creation of a new order of practitioners.

Sir CHRISTOPHER NIXON said that in seconding the proposal that Dr. MCVAIL had withdrawn the strong objection he had urged against the Midwives Bill as presented was that by registration they created a new sort of practitioner. That was completely got rid of by the proposal that there should be an annual licensing of midwives in a way similar to that in which cabdrivers and others were licensed annually. The Council had acted in a wise manner in determining to make the change, and he trusted that the proper measures would be taken to see that women practising as midwives were thoroughly trained. But the most important point of the resolutions was the penalty provided for in the case of unlicensed women practising as midwives. That was a matter that was left out of sight in the Bill presented to them. He should be glad indeed if a Bill drawn on the lines of Dr. MacAlister's resolutions were passed into law. While speaking on the previous night to a Member of Parliament he was assured that Mr. Balfour's Bill had not the slightest chance of passing this session.

Mr. HORSLEY thought it would be a great mistake if the General Medical Council were to put themselves under the Local Government Board. They were already under one Government department and that, he thought, was enough. The regulations for midwives should, in his opinion, be issued by the Midwives' Board. If the words were these: "Issued by the State Department as approved of by the General Medical Council," he should be satisfied.

The PRESIDENT said that that could be easily adjusted.

Dr. BRUCE reminded the Council that there certainly was an advantage to be obtained by the issuing of the regulations by the Local Government Board, because that Board was the one which was in communication with the medical officers of health.

Dr. MACALISTER, in order to meet Mr. Horsley's objection, moved that his fifth resolution should read as follows:—

That the conditions and regulations so framed should be subject to the approval of the General Medical Council, and if and when so approved should be issued to the local sanitary authorities by the State department which is concerned with the public health.

Mr. BROWN seconded the proposal, which was agreed to.

Mr. HORSLEY, raising another question, said that the resolutions certainly touched ordinary quackery, but quackery of an extraordinary sort was growing up because a man who took into association with himself various members of his family or several friends and formed a company might legally practise. The Council should endeavour to put an end to evasion of the spirit of the law in this way and he ventured to propose that they should adopt their own committee's recommendation:—

That no woman or any association of persons formed for the purpose shall either habitually or for gain attend, or undertake to attend, a lying-in woman unless the person attending and all the members of any association providing such attendance be licensed according to the provisions of the Act.

Mr. BROWN was quite at one with Mr. Horsley with reference to this matter, but he pointed out that it was not the subject with which the Council were now dealing. What they were dealing with were general principles on which future legislation might be based.

Dr. GLOVER: Surely there can be no harm in anticipating a possible clause in a future Bill.

Dr. MACALISTER looked upon the suggested words of Mr. Horsley as unnecessary because under the resolutions every woman practising as a midwife must be licensed.

After some conversation Mr. HORSLEY said he would not press the proposal.

The PRESIDENT: I do not think it is required. Has any other member of the Council any motion to make?

On the suggestion of Mr. BRUDENELL CARTER the word "adequate" before the phrase "safeguard in the interest of the public health" in the third resolution of the series was omitted, as was also the word "adequate" before the word "solution" in the last of the series.

The report from the committee of the Council, as amended, was then adopted unanimously and it was agreed that the President should transmit it to the Lord President as the General Medical Council's answer to the Privy Council's request for an opinion on Mr. Balfour's Bill.

The PRESIDENT, in closing the session, said that the special business for which the Council had been summoned had now been disposed of and he thought the members would

agree with him that for the resolutions they had adopted in connexion with the Midwives Registration Bill they were greatly indebted to Dr. MacAlister.

The members signified their agreement with the President by applause.

The Council rose and will meet again in regular session at the end of May next.

THE NINTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

THE Ninth International Congress of Hygiene and Demography was formally opened on Easter-day, April 10th, at Madrid, under the patronage of His Majesty Alfonso XIII. and the Queen Regent.

It was never hoped that the numbers attending the Congress at Madrid would equal the numbers that attended the Seventh Congress in London in 1891, or that attended the unexpectedly popular Eighth Congress in Budapest in 1894; but our Special Correspondent at Madrid informs us that the number of persons enrolled as members did not at the opening fall far short of 2000. Only 43 English delegates were announced as present.

There is reason to fear that some of the British delegates have been disappointed with regard to the promised 50 per cent. reduction on the French railways. On reaching the Spanish frontier it sufficed to show the card of identity at the booking office and the 50 per cent. reduction was at once granted so far as the Spanish lines were concerned. This was not the case at Paris. The application had to be made at the general management or offices of the Orleans Railway Company and not at the station booking offices and the application was followed by a delay of twenty-four hours. The safest course was to call on Dr. Brouardel, Dean of the Paris Faculty of Medicine and chairman of the Permanent International Committee, who obtained the tickets for all the French delegates without any difficulty; but this advice reached our office too late for us to warn those who were desirous of assisting at the opening of the Congress.

On Saturday evening there was a preliminary reception at the Conservatory of Music. Close upon 1000 delegates were present in full dress or in uniform and many were presented to the Minister of the Interior and the Governor of Madrid who were there to receive them. The orchestra of the Conservatory of Music played some selections and there was a well-supplied buffet where light refreshments were served. A great number of Germans were present, some in military uniforms, and in spite of the political tension there were also some American delegates.

On Sunday evening a gala representation was given in honour of the members of the Congress at the Spanish Theatre, an institution which corresponds in design to the *Comédie Française*.

On Monday afternoon the formal opening ceremony took place in the National Library under the presidency of the Minister of the Interior.

A soirée was held at the Athenæum on the evening of Monday, April 11th, and was well attended.

To-day (Friday) there will be a reception of the members of the Congress at the house of the Prime Minister, while on Saturday certain delegates are to have the honour of presentation at Court.

The proposed excursion to Andalusia more or less broke down. For a week before the opening of Congress the hotels of Madrid were full to overflowing with excursionists from all parts of the kingdom on their road to Seville for the Easter festivals. Fortunately these excursionists had left Madrid by the time the members of the Congress arrived. On the other hand, the prices at Seville went up from 200 to 300 per cent., so that it soon became impossible to guarantee accommodation to members of the Congress at any reasonable terms. The 50 per cent. reduction on the railway fares from Madrid to Andalusia held good excepting for the Algeciras-Bobadilla line, but most exorbitant charges are being made at the Seville hotels, and will be made up to April 25th. There is, however, another excursion which offers itself to the members of the Congress under much more favourable conditions. For the modest sum of ninety pesetas they may travel to Lisbon and back and thus see something of Portugal on easy terms. This will not be a joint excursion, but each delegate may go on any day he chooses.

Our Special Correspondent to the Congress speaks strongly of the absence of organisation on the part of the British delegates which, indeed, seems to us to require explanation. Great Britain is admittedly a pioneer country in matters of sanitation and it is wilfully lowering our position among nations that no proper precaution should be taken for Great Britain to speak with unanimous voice on some of the great topics of international interest that may be discussed at Madrid.

(FROM OUR SPECIAL CORRESPONDENT.)

PRELIMINARY ORGANISATION.

It is only too obvious that the Congress does not open under auspicious circumstances. Postponed for a year in consequence of the colonial wars in Cuba and the Philippine Islands, Spain is now threatened with a still greater contest against the United States. But not only are the foreign relations of the country strained to the utmost, internal politics also interfere with the Congress. An unforeseen combination of circumstances has resulted in the Senatorial elections taking place on the very day that the Congress holds its inaugural meeting. Now it so happens that the General Secretary, Dr. Amalio Gimeno, and the technical or acting president of the Congress, Dr. Julián Calleja, are both candidates for the Senate. The latter feels safe and can, without much risk, afford to absent himself from the contest; but it is within my knowledge that Dr. Gimeno has received some pressing telegrams from his electoral committee at Valencia, for which town he is candidate, urging him to be present on the day of the election. Dr. Gimeno has, however, determined to remain with the Congress, where his presence is absolutely necessary, though by so doing he weakens his chances of election to the Senate. Apart, also, from these special and personal considerations it will be readily imagined that the minds of all the organisers of the Congress are more or less distracted by the terrible crisis through which Spain is now passing. I have spoken to most of the secretaries of the Congress and I found them all of opinion that war with the United States was almost inevitable, and they naturally felt far more inclined to discuss the political events of the day than to devote themselves to the dull routine work of the Congress.

On Monday, April 4th, the secretaries and organisers were still in the occupation of two large rooms at the Ministry of the Interior overlooking the Puerta del Sol, which is the very centre—the heart, so to speak—of Madrid. On the Tuesday they removed to the *locale* of the Congress, the National Library and Museum, a majestic building on the Paseo de Recoletos, which is a continuation of the celebrated Prado, the fashionable strolling ground of Madrid. Large rooms surrounded by glass book-cases, where the national library is gradually accumulating, serve for the meetings of the sections, and other similar rooms for the offices of the secretaries, &c. There is no lack of space, even though all the basement is taken up by the Sanitary Exhibition.

Many of the delegates have arrived in advance, notably

Dr. Brouardel, Dr. Vallin, Dr. A. J. Martin, and the representatives of the Paris Municipal Council. The English delegates, on the contrary, are arriving late and Dr. Corfield, Dr. Poore, and Sir Douglas Galton have notified at the eleventh hour that they will not be able to attend. Thus three out of the four British representatives on the Permanent International Committee will not be present. This, of course, will greatly cripple the action of Dr. Arthur Newsholme (Brighton). The latter is on the Demographical International Permanent Committee. Surgeon-General Macpherson, delegate of the War Office, and Dr. Michael Beverley, delegate of the Norwich Medico-Chirurgical Society, were among the earliest British arrivals, but there were not a sufficient number of British delegates to convoke a meeting of the British section previously to the opening of the Congress so as to elect representative speakers and decide on a course of action. This want of organisation places the British delegation at a great disadvantage in face of the carefully prepared and well organised delegations of other countries. There are questions on which the British delegation could render considerable service. For instance, a severe contest is anticipated in regard to the drainage of Paris. Briefly the situation stands as follows It has been decided to purify the whole of the sewage of Paris by throwing it on the land at the rate of 40,000 cubic metres per hectare. Apart from the sewer farms established at Gennevillier the State has given 800 hectares and the town has bought 200 more hectares at Achères. This land will be laid out by the end of the year and it will then be possible to purify by land filtration 70,000,000 cubic metres of sewage per annum, or about half the sewage of the town. This has been done in accordance with the law of April 4th, 1869. A more recent law, that of July 4th, 1894, imposes the completion of the system in five years from that date—namely, before the opening of the great exhibition of 1900. For this purpose more land is to be secured on the Plateau de Mery-Pierrelaye and the Caps de Carrières de Poissy des Mureaux. There will then be no need to drain into and pollute the River Seine. The last-mentioned law also sanctioned a loan of 116,000,000 francs by means of a graduated tax on household property and it was calculated that this tax would not exceed the amount actually paid for the emptying of cesspools. In keeping with the decisions of the Municipal Council a prefectorial decree was issued on Aug. 8th, 1894, compelling householders to build water-closets protected by a syphon trap under the pan and an intercepting trap near the junction of the house drain and the sewers. Further it was enacted that every separate tenement consisting of three rooms should have a closet of its own. These rules implied such a revolution in the existing state of things that the house-owners of Paris have formed a syndicate to resist the application of the law. This syndicate attends to the interest generally of house-owners and issues a large weekly paper, but the main purpose is to prevent the construction of sanitary closets. Now this householders' syndicate has secretly secured the appointment of two representatives to the Madrid Congress. They are going to argue in favour of the separate system of drainage, for which there is much to be said, but under the cover of this theoretical question they hope to check the compulsory application of properly flushed and trapped closets within the houses. At this juncture a number of British delegates should intervene to show that the extensive experience acquired in England conclusively demonstrates that whatever system is applied in the streets, whether the separate system or not, there are no two systems for the interior of the houses. Indoors the two-gallon flush for the four-inch soil-pipe and syphon traps are absolutely indispensable. If this was done in a collective and impressive manner the little intrigue of the Paris proprietors' syndicate would be defeated and we might reasonably hope to find that great town satisfactorily drained by the commencement of next century.

Something also ought to be done by an organised and collective effort to restore the former useful and practical method of organisation which used to govern these International Congresses of Hygiene. As this method was destroyed by the organisers of the Congress held in London in 1891 the British delegation might now seek to repair the mischief which was done in England. At the opening ceremony the Acting President of the present Congress, Dr. Julián Calleja, pointed out the influence exercised by these Congresses over the legislatures of various countries and further expressed his conviction that the Congress now sitting would have more influence in this direction than any of the previous Congresses. For my part I see no reason justifying such an anticipation. So far as the number, the personal distinction and influence of the members attending is concerned this leaves nothing to be desired. But it does not suffice to crowd people together. Some means must be found of obtaining a collective expression of opinion. Formerly papers concluding with resolutions were carefully prepared, printed, and sent to all members before the Congress met. These papers were discussed at full sittings of the entire Congress held in the afternoons, the sections meeting in the mornings. The Congress then, in its collective capacity, voted on the five or six subjects which each member had had an opportunity of studying for some five or six weeks before the discussion. Such a vote naturally had a great influence. The vote of a section cannot have much effect unless confirmed at a general meeting of the entire Congress. Practically speaking, no such meetings are held except for the opening and closing ceremonies and such ceremonies only amount to an exchange of congratulations or words of welcome. Nor will the discussion in the sections have the influence that it might have had if the rules of this Congress had been faithfully carried out. According to these rules the papers to be read were to be accompanied with a summary written in French and Spanish, and these summaries, together with the text of resolutions, were to be circulated among the members a few weeks before the Congress met. The delegates would thus have some idea of the likely drift of the discussions and might prepare in advance suitable arguments so as to support or to combat this tendency. The resolutions resulting from such debates, though only adopted in a section, would certainly have some effect; but this rule has not been carried out. No summaries have been printed and nothing has been circulated among the members; thus no one knows what is going to be proposed or what arguments will be adduced. Fortunately the next Congress will in all probability meet in Paris in 1900 and the congresses held in France have in these respects always been the best organised. It is to be hoped, therefore, that the reign of chaos introduced in London in 1891 will come to a close at Paris in 1900.

THE OPENING CEREMONY.

SUNDAY, APRIL 10TH.

The large hall of the National Library was full to overflowing by two in the afternoon. It was a brilliant gathering. Uniforms of all nationalities, orders and decorations flashed in the bright light of what in England would be considered a fine summer afternoon. The Minister of the Interior occupied the chair, with Professor Brouardel and the Mayor of Madrid on his left side and the Governor of Madrid and Dr. Gimeno on his right side.

Dr. JULIAN GALLEJA, technical or acting President of the Congress, Dean of the Madrid Faculty of Medicine, and the President of the Superior Royal Council of Health, commenced the proceedings by addressing his respectful homages and salutations to Her Majesty the Queen Regent, who had so graciously consented to patronise the Congress. Then he spoke a few warm words of greeting and good wishes to the army and the navy which were fighting on behalf of the mother country in distant lands. The Acting President now turned and addressed himself to the foreign delegates who in such large numbers were attending the Congress. He congratulated himself that in spite of many complex difficulties all the countries of the Old and the New Worlds were represented at the Congress. From such a concourse of illustrious personages the cause of good sanitation would certainly derive considerable benefits. Hygiene did not consist of one particular science, but it was a combination of many different sciences. It was essentially a social science and was accessible to all. Science in general freely recognised the great benefits which sanitary science in particular had conferred on the whole civilised world. The public at large as well as technicians had applauded the progress accomplished, but there still remained much to be done. The universal theoretical recognition of the value of good sanitation was certainly a great moral triumph, but this did not suffice. In many countries the practical application of admitted principles was still neglected. To obtain the practical realisation of sanitary principles was the main purpose of such congresses. There were undoubtedly many obstacles with which scientific

sanitary reformers were but too familiar. For instance, and standing foremost, was the financial difficulty. Secondly, there was the interested opposition, notably of manufacturers and others, who find that sanitary regulations interfere with their processes of manufacture, &c. Then, again, there was the great question of personal liberty, the inviolability of the domicile, &c., which had sometimes to be set aside so as to enforce measures necessary for the preservation of public health. All these objections undoubtedly had been ably confuted by scientific sanitary reformers; still it was necessary, not only to reason out these matters, but to obtain the support of Governments so as to be able to carry out the necessary reforms. The influencing of Governments was the most practical and useful result likely to accrue from this Congress. Former congresses had already done much in this direction, but the speaker, in conclusion, expressed his conviction that the present Congress would have still greater weight on the Governments of the civilised world, adding that "the exceptional circumstances through which my beloved country is passing are, in truth, very sad and very extraordinary; nevertheless, the Spanish spirit will know how to face all obstacles as it has done in the past, and will bring all its solicitude to bear, so that nothing shall be wanting at this solemnity of peace and concord." This sentence was very loudly applauded.

Dr. BROUARDEL, Dean of the Paris Faculty of Medicine, replied on behalf of the Permanent International Committee and remarked that they had been well inspired when at Budapest they selected Madrid for their next place of meeting. The welcome they had received was no surprise, for the affability of the Spanish people had become proverbial. Their hosts had even succeeded in setting aside for a moment their terrible anxieties so as to worthily receive their guests. But this effort would not prove in vain. The patronage accorded to the Congress by the Queen Regent and the presence of the Minister of the Interior were an earnest proof of the desire of the country to advance in the cause of sanitary progress. It was most necessary that the authorities themselves should be convinced of the urgency of public health legislation. At the Official International Conferences of Venice, Paris, &c., they had already received much aid from the representatives of the Spanish Government. This would be the last congress held during this century and it must be acknowledged that the present century had done more for public health than any number of previous centuries. The century had commenced with the discovery of Jenner and was concluding by gathering the fruits of the work of Pasteur. Many old dangers to health had now disappeared. But it was more especially to the honour of our time to have understood that there are collective duties and principles that must be enforced and appreciated. The doctrine of human solidarity is now, more and more understood, nationally and internationally. We can, it is well known, prevent certain diseases. The mass of the people expect us to do so. We shall be traitors to our cause and their trust if we fail in this duty.

A German delegate, whose name was not announced, spoke on behalf of the German Government. He insisted on the growing importance of social questions, on the hatred growing amid the working classes, and the early advent of the class war. These dangers, however, might in a measure be met by good sanitary legislation destined to afford more comfort and better health to the working people.

Professor GRÜBER, on behalf of the Austrian Government, said that Spain had given the best proof of her earnestness in the cause of sanitary reform by organising so successfully the present brilliant gathering in spite of the extraordinary difficulties of the present political situation.

The delegate of the Belgian Government declared that Belgium was always eager to participate in all such congresses; and a Japanese delegate spoke, saying that Japan would not fail to avail itself of the lessons taught by the Congress.

Dr. E. VALLIN, recently Army Medical Inspector, rose in the name of the French delegation to express their thanks to the brave, generous, and chivalrous Spanish nation which was now passing so well and with so much dignity through a most difficult period in its politics. In France but little was known about Spanish hygiene, yet Spain had made great efforts of late and he felt convinced that they would have something to learn from their visit. For instance, there had been a good fight in favour of compulsory vaccination. Then all medical matters had been centralised. The teaching of hygiene was introduced into primary schools and Spain had a Society of Hygiene which published an official organ. But he had been more particularly impressed by the action of a society called the Friends of Art. This society had organised an annual festival which was called the "*Fête* of the Tree." Its object was to improve the climate and the resources of the country by the planting of trees. On that day all the school-children formed a procession under august patronage, and each child solemnly planted a tree. Generally, in the hope of reviving the silk trade, it was a mulberry tree, or else it was a linden, the royal tree of Spain. Thus at an early age the children were taught to create public property, to look forward to the future, and to do something for the public good. In this poetical manner the coming generation was taught a useful moral lesson that would have the practical result of improving the beauty and healthiness of the country.

While these speeches were being delivered there was confusion and heart-burning among the few scattered members of the British delegation. The nations were to respond in alphabetical order, and as England is spelt "Inglaterra" in Spanish we should follow close upon France. But the British delegation had not met; no one knew who was present, although it was generally felt that a Government representative should speak, and the only Government representatives present were Surgeon-General Macpherson from the War Office and Dr. Thomas Oliver from the Home Office, where he is concerned in the application of the Factory Acts. Dr. Oliver, however, was not in evening dress and Surgeon-General Macpherson, though in uniform, refused to speak and urged that the learned bodies rather than the Government officials should take the lead. Then at the very last moment Dr. Donald MacAlister, representing the University of Cambridge, was persuaded to mount the platform. Fortunately his brilliant and expansive scarlet robe produced a great effect, for his appearance elicited loud applause before he had been able to utter a single word. Speaking in English, Dr. MACALISTER said that it would be unfortunate indeed if, amid such cordial greetings, not a word was uttered on behalf of England. He spoke in the name of the University of Cambridge and as a member of the General Medical Council and on behalf of the profession generally. He need hardly say how deeply the profession in England sympathised with every effort made to improve the sanitary conditions of the Continent. Their sympathy with the international character of sanitary reform had, he trusted, found practical expression in the organisation of the International Congress of Hygiene held in London in 1891. He hoped all who were then present would recall that great gathering as a testimony of the goodwill of the British people. With regard to Spain in particular he could not remain silent. For many years Spain and England had been allies and victorious allies. Allied again to-day, not for war but for the work of peace, he hoped that their efforts would be equally glorious.

A Hungarian delegate spoke next and trusted that the Congress would see by the printed reports which the Hungarian delegation had brought with them, that great sanitary progress was being achieved in Hungary.

Dr. GIRARD, Surgeon-Major in the United States Army, was now called upon to respond. To avoid causing any irritation he had refrained from putting on his uniform and was not at all anxious to speak. The occupants of the platform, on their side, applauded his approach, and Dr. Girard so as not to incur the risk of any aggressive interruptions, spoke so low that it was impossible to hear him at a few feet from the platform. He said that he desired to express on behalf of the official delegation from the United States, their high appreciation of the very kind reception which had been shown them since their arrival in Spain. This was particularly gratifying under the present political circumstances. He wished the Congress all the success it so well deserved and hoped that before the Congress had terminated its labours the difficulties existing between Spain and the United States would be smoothed over.

The occupants of the platform could not but be gratified by these judicious remarks, while the people who crowded the hall could not hear what had occurred. Thus this episode which, if less prudently managed, might have given rise to some demonstration which would have still further complicated the political situation, passed quietly, and terminated in a graceful exchange of bows as the American delegate withdrew from the platform. Thus it

will be seen that to attend these Congresses it is sometimes necessary to possess some knowledge of diplomacy as well as of hygiene.

After a Dutch delegate had spoken in French, Professor PAGLIANI of Turin, formerly director of the Public Health Department at Rome, delivered a very eloquent speech in his own language. He saluted the Spanish people, who were upholding so well their national dignity. Spain had always been devoted to ideal conceptions and the grand ideal pursued by the sanitary reformers would travel onwards serenely in spite of temporary international convulsions. As hygienists they were not divided by political, religious, or class considerations; being devoted only to the interests of humanity, they could act independently of all these causes of dissension.

This speech, I noticed, elicited special applause from the Papal Nuncio, who was sitting close to the speaker. These words of peace were, however, followed by an emphatic political manifestation.

Dr. J. J. R. DE ARELLANO, delegate of the Mexican Government, received a regular ovation in consequence of the help offered to Spain by the Mexican Republic. Dr. de Arellano improved on this by speaking of Spain as his mother country. His Government, he added, had accepted the invitation to the Congress, firstly, so as to make a further manifestation of sympathy for Spain and, secondly, to show that the Mexican Government was anxious to associate itself with all progressive scientific movements. Finally, he wished success to the Congress so that it might benefit science and redound to the glory of Spain. These words were naturally greeted with frantic cheers. A Norwegian delegate was also much applauded because he spoke in Spanish; and then Dr. GUILLAUME, Director of the Swiss Statistical Bureau, said a few graceful words on behalf of Switzerland. The series of foreign speeches was brought to a close by General MAHMOUD PACHA, Director of the Constantinople School of Medicine, who represented the Turkish Government at the Venice and other official international conferences. Mahmoud Pacha brought the Congress back from politics into the wider and safer sphere of humanitarianism. He presented greetings and good wishes to the Congress from his august master the Sultan and declared that the Sublime Porte was eager to follow in the path of sanitary reform. He thought that science had no country, especially sanitary science, and that international sanitary congresses might well become the first link that would ultimately establish the solidarity of humanity. Thus it was reserved to the Turkish delegate to sweep away those political allusions which in spite of every precaution had trespassed upon the neutrality of the Congress, and this he did by invoking the most advanced principles of Western Europe.

The Mayor of Madrid now assured the members of the Congress of the hearty welcome they would receive from the population of Madrid, words of greeting which were still further emphasised by the Governor of the Province.

The GENERAL SECRETARY (Dr. Amalio Gimeno), who was warmly cheered by the Congress, said that never had such an assembly met under such adverse circumstances. Spain, though reluctant in the shedding of human blood, was lavish in the sacrifices it was ready to make to maintain its dignity. In spite of the present threat of war the Congress would testify to the country's devotion to the works of peace. At Budapest he had insisted on the scientific progress made in Spain, he had invited the Congress to come and see for themselves, and now he begged to thank all the foreign nations who had so well responded to this invitation.

Señor CAPDEPÓN, Minister of the Interior, then rose to pronounce the formal opening of the Congress, and to welcome, in the name of the Spanish Government, all the delegates present. This terminated the proceedings.

In the evening a gala performance was given at the Spanish Theatre, which in spite of its great size was well filled by the members of the Congress, who alone were admitted. The most celebrated actors rendered what may be considered as one of the classics of the Spanish stage, *La Niña Boba*, by Lope de Vega. The part of the heroine, played by Señora Maria Guerrero, was especially appreciated, and I am informed that this distinguished actress will soon appear on a London stage.

THE SECTIONS.

MONDAY, APRIL 11TH.

The various sections of the Congress commenced to work this morning at about 10 o'clock. Some confusion existed, and the readers of several papers failed to reach their sections when their names were called out. But the next on the list took their places and thus the business proceeded. The Bacteriological Section was one of the first to get to work, and here Dr. SPRONCH, Professor at the Utrecht University, dealt with the question of sero-therapeutic accidents. At the Wilhelmina Hospital, Amsterdam, out of 220 inoculations of serum, consisting in all of 16·7 cubic centimetres per patient, there had been 22·7 per cent. of accidents and a mortality of 20·9 per cent. But when the serum was heated, out of 103 patients treated with 18·1 cubic centimetres the accidents were reduced to the proportion of 8·7 per cent. and the deaths to 10·6 per cent. Adding to these figures those of the St. Elizabeth Hospital of Haarlem the total was 282 patients treated with 19·8 cubic centimetres of serum, resulting in 21 per cent. of accidents and 18·5 per cent. of deaths. But when the serum was heated, out of 198 cases treated with 19·6 cubic centimetres of serum there were only 5·4 per cent. of accidents and 13·1 per cent. of deaths.

In the section on Urban Hygiene Dr. LUIS MENENDEZ NOVO read a paper on the Treatment of Sewage. He thought this was the most difficult of all sanitary problems and that the employment of electricity or of chemicals had not given satisfactory results. The oldest system, which had prevailed many centuries ago in Spain, was to throw the sewage on the land, and modern science tended to show that, after all, this was the best method. Pathogenic germs were destroyed before the sewage reached a depth of 7 ft. The best ground was that which gave the freest passage to the water and to air. But the land must be allowed to rest occasionally, and no hard-and-fast rule could be established as to the amount of sewage it could receive. Means also should be taken to prevent the invasion of surrounding lands by the sewage.

Dr. KOEHLER of Berlin protested that these conclusions should have been printed and circulated among the members before the Congress met. At Dantzic and at Berlin they had good results from discharging raw sewage on the land, while at Brunswick they had had all manner of trouble in attempting a chemical treatment of the sewage.

Professor PUTZEYS of Liège, Belgium, agreed with the German delegates who had urged that there could be no general rule but each case should be treated on its own merits. In Belgium there was a great difference in places close to each other. At Liège, towards the German frontier, a very shallow soil covered a chalk deposit. Here irrigation was impossible and the sewage would sink through cracks in the chalk and pollute the water springs. Westwards of Liège the ground was of heavy clay, letting water through only when cracked by the heat of summer. To the north there was suitable sandy soil, which might be used by the inhabitants of Liège but was too far for the town of Brussels.

Dr. HENRIOT of Reims related that excellent results had been obtained for his town by throwing the raw sewage on the land.

Mr. ADOLPHE SMITH explained that this was not possible in, notably, the crowded manufacturing districts of Lancashire and Yorkshire, and as a novelty of the day, he described the working of the septic tank at Exeter.

M. DELAUNEY (France) concluded the discussion in this section by remarking that all the speakers had agreed that where suitable land could be obtained it was best to trust to land filtration. The strenuous efforts made to improve chemical processes proved that they were not satisfactory. If not absolutely perfect yet of all known methods that of utilising the soil had given the best results.

During the afternoon some members of the Congress went to witness the Basque game of tennis called *Jai-Alai*. Others went to the Faculty of Medicine, or to the hospitals of St. John and the Infant Jesus, while not a few went to the bull-fight. This evening there is a reception at the Athenæum Literary Club.

THE SANITARY EXHIBITION.

The Sanitary Exhibition is well advanced as exhibitions go, for there never was an exhibition ready on the opening day. In this case, however, quite enough is ready to interest the visitors. It is, of course, a small exhibition. Spain has but little to show in respect to manufactured apparatus, &c., bearing on health questions. Such objects have still to be imported from England, France, or Germany; but, on the other hand, there is a fair display of projects, and, better still, some record of work actually achieved. Several large rooms on the ground floor of the National Library (a building which corresponds to the British Museum in

London) have been devoted to this purpose. On the walls are hung coloured drawings illustrating various schemes of sanitary improvement; for instance, a design for a very extensive asylum for the insane, surrounded by gardens and fields, to supply wholesome agricultural occupation for the patients; then there is the plan of a large civil hospital prepared by Señor Mariano Belmas, architect, and editor of *La Higiene Popular*, a monthly publication which seeks to spread a knowledge of modern sanitation throughout Spain. Señor Belmas is the principal organiser of the exhibition and he exhibits his drawings and plans for the drainage of the towns of Salamanca and San Fernando. For these towns he proposes to employ hard-ware pipes of British manufacture, excepting of course for the main collecting sewers. Señor Wagon, civil engineer, has also a similar project for the town of Bilbao, the peculiar feature being that the sewers do not receive all the rain-water. In some districts the gutters suffice to drain off the rain-water and thus partially relieve the sewers from the sudden pressure due to storm-water. Another project, for the drainage of Barcelona, is exhibited by Señor Favia, a well-known engineer and sanitary reformer of that important commercial and manufacturing centre. Señor Fort, an architect, has a project for a popular hydropathic establishment by which he proposes that every form of bath, douche, &c., should be provided at a minimum cost for persons who have but slender means.

All these, however, are but projects. Dr. Rubio, one of the leading surgeons of Spain, has devoted a considerable portion of his private means to create a small model surgical hospital. With the aid of other subscriptions beside his own this hospital has been constructed and is now in working order. It is known as the Rubio Institute. The plans will be exhibited at the Congress and the delegates will be invited to visit the institute itself. The Laboratory of San Sebastian has a stall showing the chemical processes employed for the control of the wine and food supplies of that fashionable seaside resort. Then the military and naval departments of the State have also a laboratory and many interesting exhibits, including a plan for the Madrid military hospital prepared by the military engineering department. The Spanish Red Cross Association have a section to themselves and, among other things, they exhibit an operating table made exclusively of nickel and glass.

Dr. Comenge, Director of the Urban Sanitary Services of Barcelona, has supplied a number of diagrams showing the death-rate, birth-rate, &c., of that town. These statistics are shown by graphics which are not, as usual, drawn in parallel, vertical, or horizontal columns, but are shown in a series of circles within circles. According to the figures thus displayed, during the five years 1873 to 1877 inclusive, the average yearly death-rate was equal to 34·5 per 1000 of the population of Barcelona. The births during the same period were equal to 31·0 per 1000. Thus it will be seen that the birth-rate was below the death-rate. The authorities at Barcelona boast that great improvements have been accomplished, and in proof point to the fact that the death-rate shows a yearly average for the last five years ending 1897 of only 23·7 per 1000; this undoubtedly appears at first sight to be a great improvement, but much of its significance is destroyed by the fact that the birth-rate has fallen to 22 per 1000. Thus for a fall of 10·8 per 1000 in the death-rate there is an accompanying reduction of 9 per 1000 in the birth-rate. The great difference is, that the birth-rate is now 1·7 less than the death-rate and twenty years ago it used to be 3·5 less than the death-rate. What, however, will be of greater interest to the British public is the low death-rate from tuberculosis noticed at Barcelona. Out of each 100 deaths the proportion attributed to tuberculosis was equal in 1894 to 13·1 per cent.; in 1895 to 15·5 per cent.; in 1896 to 13·5 per cent.; and in 1897 to 14·6 per cent. During the last year the proportion of deaths due to tuberculosis in Paris was set down at 25·5 per cent. Speaking of vital statistics, Dr. César Chicote, chief of the San Sebastian Municipal Laboratory, told me that this town was divided into two parts by a large boulevard. On one side stood the old town with leaking cesspools, bad drainage, narrow streets, and many other unwholesome conditions, and here the death-rate was equal to 32 per 1000. On the other side of the boulevard stood the new town with wide streets, better drained houses, and a complete system of sewers, and the death-rate was only 17 per 1000. On my objecting that probably only rich people lived in the new town Dr. Chicote replied that such was not the case and that there were also many poor peopl in this the newest part of San Sebastian.

The Seville Institute of Hygiene, of which the chief director is Dr. Leopoldo Murga, has an interesting stall where no less than 1800 microscopic preparations will be shown dealing with many phases of bacteriological science. There are notably statistics and all the original documents relating to 480 inoculations practised by this institution for the prevention of rabies. These were commenced on March 3rd, 1895, and the figures are carried forward to March 31st of the present year. During that time it was possible to obtain possession of the dogs which had bitten 128 patients, and by inoculating rabbits it was demonstrated that these dogs were really suffering from hydrophobia. As for the other cases, the dogs were only supposed to have been rabid, but the fact could not be proved. In any case, of the 480 patients inoculated, including the 128 cases about which no doubts could be entertained, only 2 died from hydrophobia after inoculation. The process adopted is known as Dr. Ferran's intensive method—that is to say, contrary to the practice at the Pasteur Institute, the virus is not attenuated.

Among the foreign nationalities the municipalities of Paris and Berlin have voted sums so that exhibits illustrating the sanitary progress of those towns may be sent to Madrid. The town of Budapest, where the last International Congress of Hygiene was held, also sends plans and explanatory pamphlets. The Dutch contribute a number of contrivances to prevent accidents and diseases in factories, workshops, and various industries. Even from so far as Mexico come a number of well-illustrated and elaborate publications setting forth the sanitary improvements effected in that country and photographs of hospitals, slaughter-houses, asylums, &c., built in Mexico.

Several disinfecting stoves also have arrived. These are of French manufacture. The firm of Jules le Blanc, Paris, has stoves of two types: the non-portable and the portable. The former vary in size. The smallest model measures 1·05 by 1·50 metres, weighs 1050 kilogrammes, and costs £112. The boiler for the same weighs 850 kilogrammes and costs £68. The largest size measures 1·50 by 2·30 metres, weighs 2800 kilogrammes, and costs £192, with a boiler weighing 1250 kilogrammes and costing £92. The portable stoves which can be drawn from place to place by horses measure from 1·05 by 1·70 metres to 1·30 by 2·0 metres. They weigh from 1850 to 3500 kilogrammes and cost from £200 to £280. The heat produced within the stove is equal to 115°C., and on an average 12 litres of water and 3 kilogrammes of coal are consumed for each operation which should last twenty minutes. Another French disinfecting stove is manufactured by M. Fernand Dehaitre, likewise of Paris. This is a smaller stove, for it measures only 0·800 by 1·600 metres. It weighs about 1400 kilogrammes and costs £100. The great advantage offered is a simpler method of opening and shutting, which is accomplished at once by one single movement instead of by numerous bolts or screws. This reduces the risk of the accidents which are more likely to occur where there are numerous fastenings, as one of these may, through neglect, remain open. A two-horse-power boiler accompanies this stove, weighs 500 kilogrammes and costs £46. It will be seen therefore that this apparatus has, in any case, the advantage of cheapness; but it also met with the approval of the late Dr. Péan, who introduced it at the International Hospital of Paris, and it is employed by the administration of the Belgian State railways. The Madrid Municipality exhibits its disinfecting apparatus, which includes the stoves of Messrs. Geneste and Herscher, the French sanitary engineers. These stoves have often been described before, are well known, and employed in various parts of Europe. Altogether the exhibition is an important and an interesting annex to the Congress.

SCIENTIFIC GLASS-BLOWING.—Mr. Thomas Bolas, F.C.S., F.I.C., author of "Glass-blowing and Glass-working," gave an interesting demonstration before the members of the Society of Designers on Tuesday, April 5th. Among other things he showed how it is possible to blow bulbs for chemical and other purposes from a solid glass rod and exhibited a syringe constructed entirely of glass—that is to say, without the need of cotton packing. A new form of draughtsman's reservoir pen which he has invented should prove useful in applying caustic liquids in surgery and also in the application of medicaments to the eye.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated—viz.:—

Monday, April 4th:

Anatomy and Physiology.—Charles Isherwood Brierley, Yorkshire College, Leeds; Tom Bower Fawley, Yorkshire College, Leeds, and Mr. Cooke's School of Anatomy and Physiology; Frederick A. Worsley Drinkwater and William Thomas Shields, Victoria University College, Liverpool; George Rowland Roberts, St. Thomas's Hospital; James Frederick Morrison, Queen's College, Belfast; Edward Garneys Wales, Cambridge University; Sydney Lionel Prall, Stanley Hodgson, Guy's Hospital; Bernard Joseph Ward, Charles Birch, and Arthur James Arch, Mason College, Birmingham; Edward Fow Fisher and Robert Howard Newby Smith, London Hospital; John M. Herbert Munro, University College, Bristol; and Walter Rix Read, St. Bartholomew's Hospital.

Twenty-six gentlemen were referred in both subjects for three months.

Tuesday, April 5th:

Anatomy and Physiology.—George Ernest Waugh, Cambridge University and University College, London; Charles Seymour Parker, University College, London; Charles Haldane D. Robbs, Bertram S. Osmond Maunsell, and Harry Robinson Humby, St. Bartholomew's Hospital; Walter Turner Haydon and Wilfrid Fawssett, St. Thomas's Hospital; Charles Edgar Blackstone and Joseph Strickland Goodall, Middlesex Hospital; Louis Edward Stamm, John Evans, and Lionel Pern, Guy's Hospital; Alfred McCabe-Dallas, Bombay University and Guy's Hospital; James Edward Collins, London and Guy's Hospital; Louis Stephen Shoosmith and Samuel Donaldson, St. Mary's Hospital; William Payne and Henry Doyle Brice, Westminster Hospital; William Ronald Kirkness, King's College, London; Leonard Douglas Saunders and Reginald Temple Harrison, St. George's Hospital; Harold Edward Ridewood and Arthur Beaumont Waller, London Hospital; and Percy North Gleig, Charing Cross Hospital.

Twelve gentlemen were referred in both subjects, three in anatomy only and three in physiology only, for three months.

Wednesday, April 6th:

Anatomy and Physiology.—Hugh George Rashleigh, Arthur Carr Osburn, Ernest Frederick Reeve, Alfred D. Eskell Kennard, and Kenneth Weldon Goadby, Guy's Hospital; George Jacks Humphreys, John Caruthers Sale, and Ambrose Hilton John, St. Bartholomew's Hospital; Langton Fuller Hanbury, Robert Leonard Beane, and Owen Binns Gauntlett, St. Thomas's Hospital; Arthur Robartes Wellington, St. Mary's Hospital; Herbert Edward Crawley, Oxford University and St. Mary's Hospital; Edward Faulknor Ackery, Charing-cross Hospital; Charles H. Farley Bailey and Ernest Rock Carling, Westminster Hospital; Edgar W. Fox Dolman, King's College, London; Reginald J. Lambart Sladen, Charles Edward Ham, and George Sowden, London Hospital; Bransby Yule, University College, London; Adrian Caddy, St. George's Hospital; and Thomas Sanders, Cambridge University.

Anatomy only.—Alfred Newman Leathem, Charing-cross Hospital; and William Robert Ellicott, Cambridge University and Mr. Cooke's School of Anatomy and Physiology.

Eleven gentlemen were referred in both subjects and two in physiology for three months.

Thursday, April 7th:

Anatomy and Physiology.—William Spencer Lewis, Owens College, Manchester, and Mason College, Birmingham; Arthur Thomson Marshall, King's College, London; John Pugh Jones, University College of South Wales, Cardiff; Charles Montague Neale May and Oswald J. S. Damian, St. George's Hospital; Dudley Sheridan Skelton and Theophilus William Morcom, London Hospital; Sidney James Ormond, Thomas Arnold Matthews, Claude Tessier, Arthur C. Horner Gray, Michael Abdy Collins, Beethold Muir, and Hugh Kirbell Lacey, Guy's Hospital; Charles de Zouche Marshall, Albert Francis Miskin, Charles Ambrose Palmer, Harold Upcott, and Horace Haward Kiddle, St. Thomas's Hospital; William John Morrish and Cecil William Bond, St. Mary's Hospital; Albert Edward Thomas, Arthur Hastings Bostock, and Colin Sadler Hawes, St. Bartholomew's Hospital; George V. Hamlyn Fairhall, Westminster Hospital; and William Stanley Rooke, University College, London.

Ten gentlemen were referred in both subjects for three months.

Saturday, April 9th:

Anatomy and Physiology.—Perry Praime Tobit, King's College, London; Richard Smelling Roper, George Thomas Willan, Josh E. Lionel Bates, and George S. Clifford Hayes, Guy's Hospital; Frederick Ernest Wilson, Guy's Hospital and University College, London; Darrell Winn Bishop and Gerald Morgan Soper, St. Mary's Hospital; Herbert George Clitherow, Harold Rowe Jeremy and Edward Spencer Scott, London Hospital; Thomas E. Cecil Cole, St. Bartholomew's Hospital; Percy Alfred Hayne, St. George's Hospital; and Frederick Eustace Anley, Charing-cross Hospital.

Physiology only.—David Thomas Jones, Middlesex Hospital and Mr. Cooke's School of Anatomy and Physiology; Alexander Apfell Vernon, Long Island College, New York, and Mr. Cooke's School of Anatomy and Physiology; and Edward Green, Cambridge University and King's College, London.

Twelve gentlemen were referred in both subjects, one in anatomy and one in physiology only for three months.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates at the Primary Examination have passed in the subjects indicated:—

PART I.

Biology.—T. J. M. Clapperton, King's College Hospital, and A. J. Simmons, Birmingham.

Chemistry.—R. P. N. Bluett, Glasgow and St. Mary's Hospital; W. E. Cuthbertson, Bristol and Glasgow; T. D. Hemans, St. Thomas's Hospital; S. F. Hickman, Royal Free Hospital; J. E. Howrovd, Leeds; A. Kellgren, Royal Free Hospital; and H. O. Sutcliffe, Cambridge.

Materia Medica and Pharmacy.—W. P. Allen, Birmingham; R. P. N. Bluett, Glasgow and St. Mary's Hospital; E. Coulthard, Royal Free Hospital; W. E. Cuthbertson, Bristol and Glasgow; A. G. C. Davies, Guy's Hospital; S. R. Dudley, St. Bartholomew's Hospital; A. J. Kennedy and P. W. Robinson, Edinburgh; L. L. G. Thorpe, University College Hospital; and A. Wolpe, Würzburg.

PART II.

Anatomy.—W. Alcock, Sheffield; H. F. Bellamy, Charing-cross Hospital; R. P. N. Bluett, Glasgow and St. Mary's Hospital; E. Courtauld, Royal Free Hospital; C. L. Driscoll, Charing-cross Hospital; D. R. T. Griffiths, Guy's Hospital; W. T. Harris, St. Thomas's Hospital; E. H. Kenny, Manchester; A. M. Marval, Royal Free Hospital; D. W. Purkis, St. Bartholomew's Hospital; H. Richardson, Leeds; C. S. Scott, St. Bartholomew's Hospital; F. A. Segreda, Guy's Hospital; F. E. Shean, London Hospital; H. H. Sloane, St. Bartholomew's Hospital; W. S. Snell, Edinburgh and St. Mary's Hospital; W. Sykes, Manchester; and J. A. West, St. Bartholomew's Hospital.

Physiology.—J. C. M. Bailey, St. Bartholomew's Hospital; H. F. Bellamy, Charing-cross Hospital; R. P. N. Bluett, Glasgow and St. Mary's Hospital; R. V. Cowey, Edinburgh; A. W. H. Grant, Charing-cross Hospital; W. T. Harris, St. Thomas's Hospital; E. H. Kenny, Manchester; A. M. Marval, Royal Free Hospital; D. W. Purkis, St. Bartholomew's Hospital; H. Richardson, Leeds; C. S. Scott, St. Bartholomew's Hospital; F. A. Segreda, Guy's Hospital; H. H. Sloane, St. Bartholomew's Hospital; W. S. Snell, Edinburgh and St. Mary's Hospital; A. C. Stark, Westminster Hospital; W. Sykes, Manchester; and J. A. West, St. Bartholomew's Hospital.

MR. A. B. HARRIS, M.D. St. And., M.R.C.S. Eng., J.P., has been elected a member of the Falmouth Corporation.

MEDICAL MAGISTRATES. — Mr. R. Williams, L.R.C.P. Irel., M.R.C.S. Eng, of Wrexham, and Mr. R. L. Roberts, M.D. Lond., of Ruabon, have been appointed magistrates for Denbighshire.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Dr. Hermann Petersen has been recognised as *privat-docent* of Surgery.—*Breslau:* Dr. G. Born, Extraordinary Professor of Anatomy, has been made an honorary professor.—*Budapest:* Dr. Josef Bäcker, First Assistant in the Obstetric clinic, and Dr. Hugo Feleki, have been recognised as *privat-docenten* of Midwifery and Gynæcology.—*Heidelberg:* Dr. Gottlieb has been appointed Professor of Pharmacology in place of the late Dr. Schroeder. Dr. Hammer has been recognised as *privat-docent* of Internal Medicine.—*Iurieff:* Dr. Muratoff has been appointed to the chair of Midwifery and Gynæcology in place of Dr. Gubaroff.—*Leipzig:* Dr. Max Seiffert has been recognised as *privat-docent* of Pædiatry and Dr. Franz Hoffmann as *privat-docent* of Physiology.—*St. Petersburg (Military Medical Academy):* Dr. Kajan has been recognised as *privat-docent* of Surgery.—*Tübingen:* Dr. Carl Grunert has been recognised as *privat-docent* of Ophthalmology.—*Warsaw:* Dr. Shcherbakoff has been appointed to the chair of Clinical Therapeutics.—*Würzburg:* Dr. Anton Bühler has been recognised as *privat-docent* of Anatomy.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the prize list for the winter session 1897-98:—Descriptive Anatomy: Junior.—A. Charles, first prize (£3) and medal; and R. H. Oulton, second prize (£1) and certificate. Senior—J. P. Byrne, first prize (£3) and medal; and C. R. Byrne, second prize (£1) and certificate. Practical Anatomy: First year—R. H. Oulton, first prize (£3) and medal; and T. C. Fitzgerald, second prize (£1) and certificate. Second year—C. R. Boyce, first prize (£3) and medal; and J. F. Peart, second prize (£1) and certificate. Third year—J. S. P. Stewart first prize (£3) and medal; and F. G. Fitzgerald, second prize (£1) and certificate. Practice of Medicine: G. W. Little, first prize (£3) and medal; and J. S. P. Stewart, second prize (£1) and certificate. Surgery: D. A. Fitzgerald, first prize (£3) and medal; and H. H. Swanzy, second prize (£1) and certificate. Midwifery: D. A. Fitzgerald, first prize (£3) and medal; and M. Gavin, second prize (£1) and certificate. Physiology: J. F. Peart, first prize (£3) and medal; and J. P. Byrne, second prize (£1) and certificate. Chemistry:

Miss M. J. Shire, first prize (£3) and medal; and L. C. E. Murphy and W. J. O'Doherty (equal), second prize (£1) and certificate. Pathology: J. S. P. Stewart, first prize (£3) and medal; and S. R. Godkin, second prize (£1) and certificate. Physics: Miss M. J. Shire, first prize (£3) and medal; and W. B. A. Moore, second prize (£1) and certificate.

PRESENTATIONS TO MEDICAL MEN.—At a meeting on March 29th of the Brixham ambulance classes in connexion with the Great Western Railway ambulance class, on the occasion of distributing the certificates and badges to the successful candidates, Mr. George C. Searle, M.R.C.S. Eng., of Brixham, Devon, was the recipient of a Tantalus case in recognition of his instructive lectures to the class.—Dr. Taylor Grant, late medical officer of health of Shanghai, has been presented with a silver tea service and also a numerously signed address from members of the foreign and native communities engrossed on vellum and handsomely bound in morocco. He was also presented with a farewell address by the members of the medical profession in Shanghai.—At an evening entertainment on Jan. 27th last, in the Barnsley-road board school, Wombwell, in connexion with the St. John Ambulance Association, Mr. D. B. Foley, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., the lecturer of the classes, was the recipient of a marble clock and bronzes.—Mr. John Joule, L.S.A., who had been in practice for some time at Somersham, on his leaving the village was presented by the inhabitants with an illuminated address, an umbrella, and a gold-nibbed swan fountain pen.—During the past winter, at Blagdon, under the auspices of the Axbridge District Technical Committee, a series of lectures have been given to the ambulance classes for men and nursing classes for women by Mr. T. O. Halliwell, L.R.C.P. Lond., M.R.C.S. Eng., and on the recent conclusion of the lectures Mr. Halliwell received from the ladies the gift of a hall-lamp as a token of appreciation of his services.—At the meeting of the Torquay Gardeners' Association held on April 1st an illuminated address was presented to Mr. R. Hamilton Ramsay, M.D., C.M. Glasg., in recognition of the valuable services which he had rendered to the association.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Treatment of Habitual Drunkards.

THE Home Secretary has arranged to introduce and explain the provisions of the Bill with regard to the treatment of habitual drunkards on Monday, April 25th.

The Army Medical Department.

The following question in the name of Mr. Carson appears in the notice paper, viz.:—"To ask the Financial Secretary to the War Office whether the Royal College of Physicians in Ireland, acting in the interests of the public and of the Army Medical Department, has refused, as asked by the War Office, to nominate two civil surgeons to serve as surgeons with the army in the United Kingdom and at what time the reforms in the Army Medical Department promised by the Secretary of State for War will be carried into effect."

Midwives Registration Bill.

The second reading of this Bill stands as the first order on Wednesday, May 11th, but whether it is taken then depends on the progress made with the Irish Local Government Bill. According to a resolution of the House the latter measure enjoys precedence over all other orders whenever it is put down and the intention of the Government is to take its various stages *de die in diem*. If, therefore, as is by no means improbable, the Committee stage is still in progress on May 11th nothing can be done then with the Midwives Registration Bill.

HOUSE OF COMMONS.

TUESDAY, APRIL 5TH.

Examinations for Sanitary Inspectors.

Lord Edmond Fitzmaurice asked the President of the Local Government Board if he was prepared to give effect to the recommendations of the Committee appointed by the Local Government Board in 1892 to frame a scheme for a Conjoint Board of Examination for Sanitary Inspectors for the purpose set out in the Public Health Act, 1891, s. 108 (2) (d), whether the Sanitary Institute had, with the approval of the Local Government Board, enjoyed a monopoly of the privilege of such examination since the aforesaid Act was passed; and whether other bodies had applied for recognition of their examination for this purpose; and if so, the reasons why a similar recognition to that accorded to the Sanitary Institute had not been given in their case.—Mr. Chaplain replied that the Sanitary Institute was the only body that had as yet been authorised under the Act in question. Their application was received before that of any other association; subsequently applications were made by other bodies, and no authorisation had yet been given in those cases in consequence of the desire of the Local Government Board to secure the constitution of one Joint Board of Examination, to include representatives of the Sanitary Institute and other associations referred to. A committee consisting of representatives of the different bodies was appointed on the recommendation of the Board to consider a scheme for this purpose. The Board had hoped that as the result of conferences difficulties which had arisen would be met, but as yet he regretted to say this had not been the case. If these difficulties were not removed without delay it would be necessary for him to take action at once.

A Case of Rabies.

Mr. Walter Long, in reply to Mr. McKenna, said that a case of rabies occurred in Devonshire some six weeks prior to the revocation of the muzzling order in that county, but the dog was one which was believed to have been exposed to infection some six months before it was killed and which had, in consequence, been strictly isolated and kept under close supervision. The action taken by the Board of Agriculture and the local authority at the time of the original outbreak rendered the extension of the order unnecessary.

Foreign Milk.

Mr. Wingfield-Digby asked the President of the Local Government Board whether he was aware that milk from abroad, strongly impregnated with poisonous acids, was being landed in this country and though there was no guarantee to show whether the said milk came from pure and sanitary dairies or from insanitary dairies and diseased animals yet this impregnated and stale stuff was allowed to be sold as fresh new milk to the detriment of public health and the discouragement of the British farmer and all honest traders; and, if he was aware of these facts, would the Government take immediate steps to put an end to this practice.—Mr. Chaplin replied: I am not aware that the facts are as stated in the question. If I had such information it would, of course, command my attention. There is one case, I am aware, in which it is alleged that in a particular instance milk which was supposed to have come from abroad contained 40 grains of boric acid to the gallon, but proceedings in that case have been instituted and it is now awaiting decision.

Death in Prison.

Mr. Davitt addressed to the Home Secretary a series of questions with reference to the treatment and death in prison of a man named Richard Holton who had been committed to prison for seven days in default of paying a fine of five shillings by the Aston magistrates.—Sir M. White Ridley replied: I have not had time as yet to consider the report of the inquest in this case, which is one that requires to be carefully looked into; but I am anxious to give the hon. Member the fullest information possible, and the facts, so far as I have been able to ascertain them, are these. The prisoner's health on reception was recorded as good; two days after he complained of sickness, was treated in his cell, and ordered to rest for two days. At the end of the two days commencing lung trouble was discovered. He was admitted to hospital and became seriously ill. He was unfit for removal on the day for his discharge, suffering from pneumonia of both lungs, but refused to have his wife informed until the following day, when two telegrams were sent at his dictation, the first to a wrong address which the prisoner himself gave. The wife arrived at the prison at a quarter to 11 at night, and the governor, being informed by the medical officer that the prisoner though dangerously ill might last a week, refused her admission and advised her to call early the next morning. The usual regulations as to visits are suspended in cases of serious illness, and the governor has an unfettered discretion in the matter. In the present case he appears to have committed a grave error of judgment which the commissioners deeply regret; but the governor is a humane man and I see no reason to doubt that in acting as he did, contrary both to the spirit and letter of the regulations, he acted in the *bond fide* belief that the life of the prisoner was not in immediate danger.

The Institute of Preventive Medicine.

Mr. Samuel Smith asked the Home Secretary whether the licence for the practice of vivisection of the British Institute of Preventive Medicine would be transferred to the new building on the Embankment contrary to the wish of the people of London, as shown by the petition to this House signed by 183,700 persons.—Sir M. White Ridley replied: Yes, after a very full consideration of every aspect of the question I have not thought it possible to refuse to transfer the registration of the Institute to their new and more suitable premises in Grosvenor-road.

Prosser's Well at Maidstone.

Mr. Henry J. Wilson asked the Secretary to the Treasury, in view of the fact that the chemical officers of the Inland Revenue were appointed referees in disputed cases of adulteration under the Sale of Food and Drugs Act, and that water was specially excluded from the operation of that Act under Clause 3, would he state whether it was in any way the duty of the chemical officers to undertake the analysis of water for sanitary purposes and act as referees in disputed cases and under what authority the chemical officers of the Inland Revenue recently analysed the water taken from a well at Maidstone, known as Prosser's Well, and in their report expressed the opinion that the water was not liable to contamination; whether, as a consequence of such report, the application to the court to close the well was refused; was he aware that this well was in close proximity to houses in which no less than 14 cases of enteric fever occurred during the recent epidemic; and whether, seeing that the report was not signed by the chief of the laboratory, the action of these chemical officers was sanctioned by the President of the Local Government Board.—Mr. Hanbury said that the question only appeared on the notice paper that morning and asked further time to prepare his answer to it.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALEXANDER, J. W., L.R.C P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Armley Sanitary District and the Workhouse of the Bramley Union.

BLAIR, G. M., M.B., Ch.B. Glasg., has been appointed House Physician to the Royal Hospital for Diseases of the Chest, City-road, London.

BOVEY, THOS. W W., M.R.C S.Eng., L.R C.P.Lond., has been appointed House Physician to the Norfolk and Norwich Hospital, Norwich.

BOWIE, J. C., M.B., C.M. Aberd., has been appointed Medical Officer and Public Vaccinator for the parishes of Sandsting and Aithsting, Shetland.

BRUCE, J., M.B., C.M. Edin., has been appointed an Honorary Medical Officer to the Leancholl Hospital, Forres.

BURTON, H., L.R.C.P. Irel., M.R.C.S., has been appointed Medical Officer of Health by the Marp'e Urban District Council.

CHILDE, C. P., F.R.C.S., L.R.C.P. Lond., has been appointed an Honorary Medical Officer to the St. John's Convalescent Home, Southsea.

CRAWFORD, D., M.B., C.M. Edin., F.R.C.S., has been appointed an Honorary Surgeon to the Stanley Hospital, Liverpool.

DU CANE, EDGAR, B.A., M.B., B.Ch., has been appointed Resident Medical Officer to Christ College, Brecon.

FAIRBANKS, WM., M.D. Edin., C.M., has been appointed Medical Officer for the Workhouse of the Wells Union.

FOWLER, J. S., M.B., C.M., M.R.C.P. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed Extra-mural Clinical Tutor to the Edinburgh Royal Infirmary.

HICKMANN, J. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Coleford Sanitary District of the Frome Union.

HODGSON, G. G. G., L.R.C.P. Lond., M.R.C.S., has been appointed Police Surgeon for the Chertsey Division, Surrey, vice H. E. Daniell resigned.

MACLENNAN, E. M., M.B., C.M. Aberd., has been appointed an Honorary Medical Officer to the Leancholl Hospital, Forres.

MASON, F. W., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the No. 4 District of the Flaxton Out-relief Union.

MAXWELL, J. B., B.A. Cantab., M.R.C.S., L R C P., has been appointed Resident Medical Officer to the Royal Hospital for Diseases of the Chest, City-road, London.

MILWARD, VICTOR F., B.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R C.P. Lond., has been appointed Resident Surgical Officer to the General Hospital, Birmingham.

RENSHAW, C. J., M.D. St. And., M.R.C.S., has been re-appointed Medical Officer of Health by the Ashton-upon-Mersey Urban District Council.

ROBERTS, G. W., M.D. St. And., L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Denbigh Urban District Council.

ROBINSON, B. S., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Stourport Urban District Council.

ROWE, W. T., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon to the West London Hospital, Hammersmith-road, W.

SCOTT, F. G., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Gillingham Sanitary District of the Medway Union.

SMITH, J. W., M.D. Edin., C.M., has been re-appointed Medical Officer of Health by the Ryton Urban District Council.

STABB, ARTHUR F., M.B., B.C. Cantab., M.R.C.P., has been appointed Assistant Obstetric Physician to St. George's Hospital, London.

TURNER, A. C., M.B., C.M. Edin., has been appointed an Assistant Medical Officer to the Fisherton Asylum, Salisbury.

WILSON, A., M.B., C.M. Glasg., has been appointed Ettles Lecturer at Inverness.

YOUNG, J. Y. S., M.B., C.M. Edin., has been appointed a Resident Medical Officer to the Convalescent House, Corstorphine, Edinburgh.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRKENHEAD UNION.—Assistant Medical Officer for the Infirmary, Workhouse, and Schools. Salary £80 per annum, with board, washing, and apartments, but no extra fees. Applications to the Clerk to the Guardians, Clerk's Offices, 45, Hamilton-square, Birkenhead.

BOROUGH OF MIDDLESBROUGH.—Medical Officer of Health. Salary £350 per annum, payable monthly. Applications to the Town Clerk, Middlesbrough.

CHESTER GENERAL INFIRMARY.—Assistant House Surgeon for one year. Salary £40 per annum, with residence and maintenance in the house.

CITY OF LONDON FREEMEN'S ORPHAN SCHOOL AND THE LONDON AND ROGERS ALMSHOUSES, Ferndale-road, Brixton.—Medical Officer, married. Salary £125 per annum. Applications to the Town Clerk's Office, Guildhall, E.C.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c.

FLINTSHIRE DISPENSARY.—Resident House Surgeon. Salary £120 a year, with furnished house, rent and taxes free, also coal, light, water, and cleaning, or in lieu thereof the sum of £20 per annum. Applications to the Secretary, Board-room, Bagillt-street, Holywell.

GENERAL HOSPITAL, Nottingham.—House Surgeon for two years. Salary £100, rising £10 a year to £120.

GENERAL INFIRMARY, Gloucester, and GLOUCESTERSHIRE EYE INSTITUTION, Gloucester.—Assistant Surgeon.

HANTS COUNTY ASYLUM, Fareham.—Third Assistant Medical Officer, unmarried. Salary £100 per annum, increasing to £125 after twelve months' service, with furnished apartments, board, washing, and attendance.

HOSPITAL FOR WOMEN AND CHILDREN at Leeds.—Non-resident House Surgeon for twelve months. Salary £90.

MIDDLESBROUGH COUNTY BOROUGH ASYLUM, Cleveland, Yorkshire.—Assistant Medical Officer, single. Salary £100 per annum, with furnished apartments, board, washing, and attendance.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-upon-Trent.—Assistant House Surgeon for six months, board, apartments, and washing provided.

ROUSAY PARISH COUNCIL, Orkney.—Resident Medical Officer. Salary £51 sterling per annum. Applications to the Clerk of the Parish Council, Rousay, Orkney.

ROYAL ALBERT HOSPITAL, Devonport.—Resident Medical Officer for two years, unmarried. Salary £100 per annum, with board and lodging.

ROYAL CORNWALL INFIRMARY, Truro.—Honorary Ophthalmic Surgeon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiners.

SCARBOROUGH HOSPITAL.—Senior and Junior Resident House Surgeons. The former for twelve months, salary £80 per annum, with board and lodging, and the latter for six months, salary at the rate of £50 per annum, with board and lodging.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—Assistant House Surgeon. Salary £30 per annum, with board, lodging, and washing.

ST. PAUL'S HOSPITAL FOR SKIN AND GENITO-URINARY DISEASES, London.—Honorary Surgeon and Honorary Assistant Surgeons, Applications to Mr. T. J. Savage, 60, Moorgate-street, E.C.

THE HOSPITAL OF ST. FRANCIS, 145, New Kent-road, London, S.E.—Assistant Surgeon and Assistant Physician (out-patients only).

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £50 per annum, with board, residence, &c.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—House Surgeon for about two months. Salary 3 guineas a week, with board, washing, and travelling expenses. Also House Physician, and to act as Medical Registrar and Pathologist, for one year. Salary £100 a year, with board, lodging, and washing. Also House Surgeon, and to act as Surgical Registrar, for one year. Salary £100 a year, with board, lodging, and washing.

YORK DISPENSARY.—Resident Medical Officer to visit and attend (including midwifery), the sick poor at their own homes, unmarried. Salary £150 a year, with furnished apartments, coals, and gas. Applications to W. Draper, Esq., De Grey House, York.

Births, Marriages, and Deaths.

BIRTHS.

BERRINGTON-STONER.—On April 9th, at Rio Lodge, Hove, the wife of C. Berrington-Stoner, D.D.S., L.D.S., of a son.

BUCKMASTER.—On April 5th, at 16, Northwick-terrace, N.W., the wife of George A. Buckmaster, M.D., of a daughter.

BROOM.—On Feb. 14th, 1898, at Sandgate, near Brisbane, Queensland, the wife of Arthur Robert Broom, M.R.C.S. Eng., L.R.C.P. Edin., of a son.

CULMER.—On March 30th, at Nassau, Bahamas, the wife of John J. Culmer, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MEYRICK-JONES.—On April 8th, at Church-street, Crewkerne, Somerset, the wife of A. M. Meyrick-Jones, M.B., B.S., F.R.C.S., of a son.

STANLEY.—On April 2nd, at Brabourne, Kent, the wife of Hubert Stanley, M.B. Cantab., M.R.C.S., L.R.C.P., of twins—boy and girl.

SYLVESTER.—On April 8th, at Leiston, Suffolk, the wife of Herbert Mayris Sylvester, M.R.C.S. Eng., of a son.

WAINEWRIGHT.—On April 2nd, at 39, Lee-terrace, Blackheath, the wife of Robert S. Wainewright, M.D. Lond., of a daughter.

MARRIAGES.

SAVORY—LEIGH BENNETT.—On April 13th, at Thrybergh, by the Rev. Gray Granville, rector of Ilam, uncle of the bride, assisted by the Rev. Canon Bartlet, Horace Savory, M.A., M.B., of Haileybury College, to Mary Ellinor Leigh, second daughter of the Rev. Canon Leigh Bennett.

SEAL—WARN.—On March 12th, at St. Paul's Cathedral, Calcutta, Charles Edward Baldwin Seal, M.R.C.S., L.R.C.P., of Darjeeling, to Jessie, second daughter of William Warn, of Tetbury, Gloucestershire.

DEATH.

KING.—On April 7th, at the English Nursing Home, Cairo, Thomas Percy King, M.B., B.C. Cantab., M.R.C.S., son of the late Dr. Thomas King, of Rochford, Essex.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, April 14th, 1898.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.).

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.) St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (19th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. C. P. White: (1) Intestinal Obstruction due to Cicatricial Stricture of the Small Intestine; (2) Columnar-celled Carcinoma of the Œsophagus.—Mr. d'Este Emery: Secondary Growths from a Case of Carcinoma of the Breast.—Mr. G. B. Hunt: Extreme Contraction of the Stomach with some remarks on the Pathology of the Condition.—Dr. L. Dickinson: An Aneurysm of the Thoracic Aorta which Ruptured Externally.—Dr. P. Weber: Liver showing an Early Interlobular Type of Cirrhosis from a Case of Suppurative Pylephlebitis.—Dr. E. Bradford: Hæmatoma in a Hydronephrotic Kidney.—Dr. Garrod: A Case of Carcinoma of the Œsophagus Perforating the Aorta.—Dr. L. Freyberger: (1) A Brain with Three subsequent Hæmorrhages and a Heart from the same Case showing a well-developed Musculus Papillaris on the Mitral Valve; (2) The Minute Structure of an Anæmic Infarct of the Lung. Card Specimens:—Dr. C. D. Green: (1) A Stomach with Two Perforating Ulcers and a Fistulous Communication with the Colon; (2) A Lobulated Fibroma of the Nipple.

WEDNESDAY (20th).—ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Gt. George-street, Westminster, S.W.).—7.30 P.M. Papers:—Major H. E. Rawson: Anticyclonic Systems and their Movements.—Hon. F. A. Rollo Russell: Results of Observations on Haze and Transparency in 1897.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Mr. H. Morland: Exhibition of Diatoms.

NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital).—8 P.M. Exhibition of Cases.

THURSDAY (21st).—SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Clinical Cases. Paper:—Mr. H. T. Pechell: On the Use of Ormsby's Ether Inhaler in General and in Dental Surgery, with remarks on Etherisation and on Dilute Solutions of Chloroform.

FRIDAY (22nd).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. F. Taylor and Mr. A. D. Fripp: A Case in which a Renal Calculus was Detected by the Roentgen Rays and successfully Removed.—Dr. J. R. Bradford: A Case of Thrombosis of the Superior Mesenteric Vein causing Intestinal Obstruction.—Mr. R. Johnson: A Case of Tuberculous Peritonitis in which Symptoms of Intestinal Obstruction resulted probably from Thrombosis of the Superior Mesenteric Vein.—Dr. L. Dickinson and Mr. W. A. Hubert: Raynaud's Gangrene in connexion with Parturition.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

MONDAY (18th).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Lt. G. Reid: Sanitary Appliances.

WEDNESDAY (20th).—EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Mr S. Stephenson: Ophthalmia in Newly-born Children. (Post-Graduate Course.)

THURSDAY (21st).—THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. J. W. Clarke: Details of Plumbers' Work.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

UNSOUGHT PUBLICITY.

DR. THOMAS G. NICHOLSON writes to us to say that he recently took a house at Marlow and that paragraphs promptly appeared in the local journals unknown to, and unsought by, himself. On his return to town he found a letter awaiting him from the editor of the "principal paper" asking for a paragraph containing personal particulars. Dr. Nicholson naturally enough replied that he could do no such thing, although he had no doubt that the editor was actuated by the kindliest of motives. The mistaken kindness of friends and would-be friends has before now placed medical men in a very unpleasant situation, but in these days of commercialism the only thing to do is to follow Dr. Nicholson's example—namely, protest and, if possible, prevent such action.

POLITICS OR PRACTICE.

To the Editors of THE LANCET.

SIRS,—There has appeared quite recently in several local papers this advertisement:—

> "WANTED, a RESIDENT MEDICAL PRACTITIONER for eight large villages. A splendid opening for an energetic man who would attend to his profession.—Address for particulars, Mr. —— of ——."

I applied for particulars and received a letter which purported to come from Mr. —— making an appointment for me to meet Mr. X. I wired to Mr. —— suggesting a more convenient day and received a letter from Mr. X agreeing to my plan. I was rather puzzled to account for both letters being apparently *written by one hand*. On my arrival I was met by Mr. ——, who had been deputed by Mr. X. to take me to the latter's house, and as we journeyed thither I learned that Mr. —— was acting only as advertising agent and had otherwise nothing to do with the matter. He said that Mr. X. had just been defeated in the county council election by the resident medical man, of whose existence I had not heard when I set out on my voyage of discovery; that the said practitioner was a red-hot politician, and that, of course, he could not attend to politics and his practice, and that some people were complaining of the practitioner's neglecting them.

When we arrived at a road branching off to Mr. X.'s house I became curious to know where the doctor lived. "Straight on that way, near the bottom of the village," said the deputy. "Thank you," said I, "Good day, I will go on and see him"; and I left Mr. ——. I found

the doctor knew all about it. One man had been down already, and did not come near him. He, however, did not think the chances very good. Mr. —— had voluntarily assured the doctor of his acting only as an agent in the business, of his regret and disapproval, and of his personal intention to retain him for the family doctor as he had always been. Though I do not for an instant suggest that Mr. X. is not animated by the most disinterested motives (by exactly the same public spirit, indeed, as no doubt prompted the offer of his services to his neighbours as their county councillor) still I hope that my plain narrative of the facts will prevent all other medical men seeking an opening from proposing to supply his "want" in this case.

I am, Sirs, yours faithfully,

March 29th, 1898. THOS. M. WATT.

THE TREATMENT OF OTORRHŒA.

DR. J. R. LOGAN of the Liverpool Infirmary for Children, writing in the *Caledonian Medical Journal*, recommends that in otorrhœa the auditory meatus should be cleansed by a preliminary syringing or douching followed by wiping with a series of cotton-wool swabs or brushes. If these are sufficiently soft and made to project for an inch or more beyond the point of the probe to which they are attached they furnish a safe and very efficient means of removing the discharge. For subsequently keeping the meatus clean he prefers the double cyanide of zinc and mercury, a substance which was introduced as a surgical dressing by Lord Lister in 1893. There are two varieties of it in the market, one of them having the natural white colour and the other being tinted pink by means of rosolane (hydrochloride of mauvine). The coloured salt when rubbed in a mortar with water forms a soft flocculent powder, which remains much better in suspension than the white substance. The proportion usually employed is one part of the cyanide to twelve or twenty of water, and two or three drops of the warm mixture are instilled into the deepest part of the meatus by means of a fine glass pipette, the point of which is provided with a piece of crow-quill sized rubber tube projecting about 1 in. beyond the glass. This is repeated two or three times a week, but if convenient it may be done daily. By this means a recent case of otorrhœa may be kept absolutely sweet and the most profuse and offensive discharge may be rendered quite free from smell by a single operation.

A QUESTION OF TREATMENT.

To the Editors of THE LANCET.

SIRS,—Can any of your readers kindly offer a hint as to treatment in a case of redness of the integument of the nose? The patient is a woman, aged twenty-eight years, and she used to suffer frequently from dyspepsia, but under appropriate dietary this is seldom *en évidence* now. The trouble seems to be chiefly due to dilatation of the small veins and to be passive in character, but the colour occasionally becomes vividly red and this chiefly when, owing to some indiscretion, an attack of indigestion occurs. Massage appears to have but little influence on the case. I am, Sirs, yours faithfully,

April 11th, 1898. VENULE.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—I desire to draw the attention of charitable members of the profession to the case of the widow and family (five in number) of the late John Page Hentsch, M.R.C.S.Eng. and L.S.A., of Coldharbour-lane, Brixton, S.W. Mr. Hentsch died in January last after an illness of nearly a year's duration, leaving those dependent upon him totally unprovided for. By the aid of friends it is hoped to provide for three of the children, but pecuniary help is wanted to tide the family over the present period of distress. I shall be glad to receive and acknowledge on behalf of the widow and family any contributions which may be sent to me. I am, Sirs, yours faithfully,

410, Brixton-road, S.W., April 11th, 1898. G. DAVID KNIGHT.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—May I ask if you or any of your readers know of any home where a lady can be received who a year ago underwent the operation of colotomy for stoppage of the bowels? She would require medical and nursing attention and board. She has £52 a year and is sixty-six years old. I am, Sirs, yours faithfully,

April 12th, 1898. G. S.

"AN OBSTINATE CASE OF HERPES."

To the Editors of THE LANCET.

SIRS,—I have had in my hospital and private practice several such cases of chronic or recurrent herpes præputialis as is described by Mr. J. Firench Blake in THE LANCET of April 9th. He should be quite sure of the absence of a specific cause and should ascertain whether his patient's wife suffers from leucorrhœa; if so and this is cured the herpes will probably disappear. Excessive coitus is, of course, a frequent cause. In several cases I have seen well-marked varicose veins in the prepuce and around the glans. In two of these cases I have tied such veins and the herpes disappeared permanently. I agree with Unna in thinking that many of these recurrent cases are due to the compression of nerve terminals brought about by venous engorgement, and certainly find that most cases exhibit more or less enlarged veins. As regards treatment, if any one of the above-mentioned causes be present it should be remedied. If the foreskin be long it should be removed. Sponging with cold water should be practised morning and night. The herpes having been for the time being removed coitus should be forbidden for some weeks and glycerine and tannin, or, better still, sulphate of copper (20 gr. to 1 oz.), or sulphate of zinc (40 gr. to 1 oz.), applied to the part on lint. Tincture hamamelidis may often also be found useful, but whichever is selected it should be frequently removed, the part washed, and the application renewed, and in all cases the foreskin should be separated from the glans by the lint. Greasy applications should never be applied during the interval of the attacks and during the attack I think that cocaine while relieving the irritation tends to increase the trouble.

I am, Sirs, yours faithfully,

Frognal, N.W., April 11th, 1898. G. HAY REYNOLDS, M.B. Aberd.

TO CONTRADICT A RUMOUR.

To the Editors of THE LANCET.

SIRS,—It has come to the knowledge of the directors of Dr. Tibbles' Vi-Cocoa (1898) Limited, that a report is in circulation that a Mr. Harness is in some way connected with or interested in the business of Dr. Tibbles' Vi-cocoa (1898) Limited. Will you permit me to contradict this report publicly in your columns? It is wholly without foundation. I speak with authority on the matter, for I am now secretary to the present Vi-Cocoa Company; I was secretary to the former Vi-Cocoa Company during the whole period of its existence; and I was in the employ of the owners of the business before either company was formed. Hence I am in a position to state positively that no person of the name of Harness has ever been in any way concerned or interested in or in any way connected with that business or either company.

I am, Sirs, yours faithfully,

G. BROOKE SMALLEY,
Secretary to Dr. Tibbles' Vi-Cocoa (1898) Ltd.

Bunhill-row, London, E.C., April 13th, 1898.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In your last issue, under the head of "Appointments," you have it that Dr. Bond is re-appointed medical officer of health for Chepstow. It is an error. I am medical officer of health for the *urban* district of Chepstow, Dr. Bond holds a large *combined* district of which the Chepstow rural district forms part; hence the mistake.

I am, Sirs, yours truly,

Melrose House, Chepstow, April 12th, 1898. E. P. KING.

*** We regret the error.—ED. L.

Dr. T. R. Atkinson.—The names of numerous institutions will be found in our advertisement columns, also in Burdett's "Hospitals and Charities." Probably, however, most establishments would charge a higher fee than that mentioned. As to the "cure" mentioned we should advise our correspondent to have nothing to do with it.

C. O. H.—The plate is incorrect, but we doubt if it can be called illegal. The offenders would fall back upon the double meaning of the title of "Dr." as a defence. The matter is one that should be referred to the General Medical Council.

An Old L.S.A. Eng. cannot practise in all parts of America on his diploma. He will find in THE LANCET of Sept. 12th and Oct. 3rd, 1896, an account of the formalities required by the different States.

J. D. M. would be glad to know of a thoroughly reliable institution for inebriates where a man could be received at a moderate charge.

Assistant.—The fee belongs to the principal.

During the week marked copies of the following newspapers have been received: *Nottingham Guardian, Berkshire Chronicle, Wiltshire Times, Consett Guardian, Westmorland Gazette, Halifax Guardian, Hereford Times, New York Herald, Lytellton Times, Todmorden Advertiser, Times of India, Pioneer Mail, Scotsman, Yarmouth Advertiser, Oxford Times, Architect, Derby Express, Rugby Advertiser, Hastings Times, Builder, Glasgow Herald, Isle of Wight Observer, Liverpool Daily Post, Englishman (Calcutta), Southend Echo, Middlesbrough Evening Telegraph, Bristol Mercury, Lancashire Express, Dundee Courier, South Wales Daily News, Llandudno Directory, Cheltenham Mercury, Hawick Advertiser, Yorkshire Post, Eastern Morning News, Western Morning News, Leeds Mercury, Brighton Argus, Salisbury Journal, Leek Times, Croydon Guardian, Enfield Chronicle, Walsall Advertiser, Sussex Daily News, Newport Advertiser, Herald of Wales, Birmingham Daily Post, Southampton Observer, West Briton Advertiser, Hemel Hempstead Gazette, Manchester Courier, Sanitary Record, Free Press (West Bromwich), Mining Journal, Local Government Chronicle, Reading Mercury, Brighton Gazette, Public Health Engineer, Surrey Advertiser, Hertfordshire Mercury, Local Government Journal, City Press, La Revue Mame (Paris), Vegetarian, Civil and Military Gazette (Lahore), The Age (Brisbane), Eastern Daily Press, Manchester Evening Chronicle, Hong-Kong Weekly Press, Notes and Queries, Lloyd's Weekly Newspaper, Kendal County News, West Middlesex Herald, Lytham Times, Kidderminster Times,* &c., &c.

Communications, Letters, &c., have been received from—

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

ABSTRACT OF

The Hunterian Lectures

ON

THE SURGERY OF THE KIDNEY.

Delivered before the Royal College of Surgeons of England on March 21st, 23rd, and 25th, 1898,

BY HENRY MORRIS, F.R.C.S. ENG.,

SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE II.[1]

Delivered on March 23rd.

RENAL CALCULUS; THE DIFFICULTIES AND ERRORS IN DIAGNOSIS IN THEIR RELATION TO EXPLORATION OF THE KIDNEY; UNSUSPECTED, QUIESCENT, AND MIGRATORY CALCULI.

MR. PRESIDENT AND GENTLEMEN,—To-day I wish to draw attention to some renal calculous disorders. If I put them in the very forefront of surgical affections of the kidney I do so for the following reasons: 1. They are the most frequent and most painful of the surgical diseases of the kidney. Probably no disease, except acute tetanus, is capable of causing worse suffering. 2. Renal calculus, whilst slowly destroying the kidney, often physically disables its victim by its unrelenting irritation and its unyielding resistance to every form of medical and dietetic treatment. 3. No disease gives rise to such a variety of morbid changes in the kidney as calculus and none is more certainly fatal when allowed to progress without surgical interference. 4. Few operations in surgery are so successful as nephrolithotomy and no great operation is followed by a smaller mortality. Nephrolithotomy gives absolute cure, saving the kidney from progressive destruction and the patient from what at any moment may prove to be an imminent danger to life. 5. Renal surgery will grow in confidence and in favour with the profession and the public as nephrolithotomy anticipates and displaces nephrotomy and nephrectomy. I attempted to show in the latter part of the first lecture that nephrectomy is being rapidly restricted in its application as advances are made in ureteral operations. It may also be safely asserted that nephrotomy, at present the most frequent operation resorted to for calculous affections, will be required but rarely if nephrolithotomy is performed more early and more often. Calculous pyonephrosis is the result of long-standing irritation and progressive destruction of the kidney, and there is no reason why it should ever occur if physicians would recommend and surgeons would practise early operations for stone in the kidney. That this is a consummation much to be desired is seen by comparing the mortality of nephrolithotomy with that of nephrotomy and nephrectomy for calculous conditions. The figures are as follows:—Nephrolithotomy mortality, 2·9 per cent; nephrotomy, 23·25 per cent.; nephrectomy, 29·4 per cent. 6. Another reason why calculous disorders take so prominent a lead among the surgical affections of the kidney is because of the difficulties and errors attending their diagnosis.

When calculi have been previously passed, when well-marked attacks of renal colic occur, when crystals of uric acid or calcium oxalate are frequently found in the urine, and when the urine is intermittently mixed with a good deal of blood or persistently contains a microscopic quantity, there are the strongest *a priori* grounds for thinking that a stone is present. This evidence is strengthened if attacks of colic and hæmaturia are readily induced by exercise or jolting and readily subside with rest and if a sharp pain or distinct tenderness is always caused by bimanual examination of the renal region. In many cases, however, mistakes in diagnosis are bound to arise. Morbid conditions other than stone will be found from time to time in cases in which the character of the pain and the state of the urine point to calculus as the probable cause. These mistakes are apt to excite a prejudice against renal exploration; but the results obtained by those who have had large practice in renal surgery ought to correct this. The experience gained by operations has taught us much as to what the conditions are which cause symptoms typical of stone when no stone exists.

In 1892 I published some lectures[2] on the conditions simulating renal calculus as verified by surgical exploration in 28 cases. To these I now add 16 cases, making 44 in all. In a few instances a calculus was possibly in the ureter at the time of the exploration, because one was passed some little time subsequently. But in the greater number of the 44 cases some other morbid state of the kidney was found and remedied. It is certain that the diagnosis of calculus, though incorrect, was advantageous to these patients for the very reason that it led to the exploration and in this way to the discovery of the true cause of the disease. The expression "negative exploration" is often applied to every operation in search of renal calculus which does not result in the discovery of a stone. This expression is very misleading. It is not a "negative" result to find and excise commencing foci of tuberculous disease, to fix a misplaced or freely shifting kidney, to open and scrape away half a dozen small abscesses or suppurating cysts, to excise a solid renal or peri-renal tumour or a tense cyst, to liberate a kidney hampered by tough adhesions, or to detect and divide a ureteral stricture or obstructing valve. Yet these are some of the conditions which have been met with in the search for stone in the kidney and which in many instances have been most successfully cured. I have explored several cases in which the diagnosis was very doubtful but the severity of the sufferings so intense that the patients have willingly submitted to an operation. The exploration has proved the absence of a calculus but has revealed a degree of mobility behind the peritoneum altogether out of proportion to any mobility detectable by clinical examination. In these cases complete relief has been obtained by nephropexy. In other cases I have found instead of calculus the kidney more or less displaced, and though little, if at all, moveable yet greatly engorged with venous blood owing to distortion of the veins at the hilum. In other cases, again, the kidney has been swollen and congested with venous blood, obstructed by the pressure of tough and condensed perinephric cellular tissue. The relief which is given by the so-called "negative exploration" in cases such as I have referred to is, to my mind, a striking illustration of the indirect benefits which nephrolithotomy has conferred on suffering humanity.

Another important class of cases in which the symptoms simulate renal calculus is *ureteritis*, a disease to which more attention seems to have been given in France and Germany than elsewhere. As long as nephrotomy was limited to cases in which the kidney was converted into a great abscess the ureter was never seen in the living human body; but since nephrolithotomy took its place as a recognised operation, and an exploratory incision with a view to nephrolithotomy has been considered justifiable because proved to be safe, the morbid states of the ureter have by degrees come to be better known and operative measures have been adopted for their improvement or cure.

I feel sure that cases of so-called nephralgia will become rarer and rarer, (1) if due care is used in the clinical observation of patients supposed to be suffering from renal calculus, (2) if proper care is taken in the selection of cases for operation, and (3) if a more thorough and methodical exploration is made of the kidney *and ureter* than is, I believe, customary at present.

There are many conditions outside the kidney, as well as those connected with that organ, which give rise to symptoms suggestive of renal calculus. I have known instances of each of the following diseases being the subject of this mistake. (*a*) Gastric ulcer; (*b*) malignant and tuberculous growths in the intestines; (*c*) intestinal adhesions, whether involving the renal pedicle or not; (*d*) aortic or cœliac aneurysm stretching the ureter or renal vessels; (*e*) spinal disease; (*f*) vesical calculus; (*g*) abscess and calculus in the prostate; (*h*) growths in the bladder; (*i*) ovaritis; (*j*) tuberculous disease of the Fallopian tube; (*k*) a gallstone in the cystic duct. Still, there certainly are cases in which neither within nor without the urinary organs has anything been discovered to explain continuous discomfort or attacks of paroxysmal pain in the renal region, and yet complete relief has followed an exploratory operation. These are the cases which we are

[1] Lecture I. was published in THE LANCET of April 16th, 1898.

[2] Brit. Med. Jour., vol. i., 1892.

apt to call nephralgia and these the only operations which we can properly speak of as "negative explorations." Nor do I think we must quite rely upon a statement which has been put forward with some authority to the effect that paroxysmal renal pain or so-called nephralgia is never associated with neuralgia in other situations and has never been relieved or cured by anti-neuralgic remedies. We do not get well-marked cases of the kind in this country, nor do I suggest that all the cases of renal pain which are cured by renal exploration are of malarial origin; but nephralgia of malarial origin would seem to be known in other countries, and there is reason therefore for thinking it may from time to time be met with in our own in persons who have lived much abroad.

I recall a short but suggestive contribution to the *Medical Times* on Nephralgia due to Malarial Poisoning, by an old pupil, Mr. F. W. Kirkham, who was formerly surgeon to the Royal West India Mail, and whose name is associated with a most successful case of ureterotomy for impacted calculus.[3] Mr. Kirkham therein reports the case of an engineer whom he was called to see when at Colon, in the Isthmus of Panama, who had twice suffered from intermittent fever. This young man (aged twenty-five years) was seized suddenly with severe dull aching pain in the right loin, varied at intervals by paroxysms of severe shooting pains extending down the corresponding thigh. After lasting about four hours they passed off attended by profuse perspiration. Similar attacks occurred on the two following days, and again on the fourth day, when he was first seen professionally. Mr. Kirkham found that the temperature was 102·4° F., the pulse was 108, the skin was dry, and the tongue was clean. There was no enlargement of the liver, spleen, or kidney, but there was tenderness in the right loin. The urine, though alkaline, was free from any abnormal sediment. Morphia relieved pain and promoted sleep, and 20 grains of quinine prevented the recurrence of the attack on the following day, and 15 grains had the same effect on the day after. As soon as the quinine was discontinued the attacks recurred, but a return to the quinine and subsequently a change of climate enabled him to enjoy perfect health. Mr. Kirkham adds: "During the past two years I have had four patients under my care who after recovering or during their recovery from malarial fevers have been seized with daily recurring attacks of pain in the region of the kidney, presenting symptoms very like those due to the passage of a renal calculus."

Tiffany of Maryland[4] speaks of having seen a number of cases of malarial hæmaturia in which it would seem that a history of intermittent or remittent fever was often wanting, but the patients had a sallow complexion, which, however, might have been wrongly attributed to the affection for which surgical relief was sought.

Hopes were entertained that the Roentgen rays would be of service in determining the presence or absence of renal calculi, but hitherto they have afforded but little help in this direction. In time possibly they will be able to render more assistance than they have yet done, but if they demonstrate with certainty the presence of a calculus without being also able to reveal the other morbid conditions remediable by operation which mimic calculus they will, I fear, be the means of putting back renal surgery by deterring many patients from submitting to surgical explorations who can be cured by no other treatment than an operation.

"UNSUSPECTED RENAL CALCULUS."

I have pointed out that there are numerous morbid conditions other than renal calculus which cause typical renal colic. Conversely, there are many cases in which the symptoms due to renal or ureteral calculus are not referred to the kidney or ureter at all, but to some other organ. It is also well known that a calculus for a long time may cause no symptoms whatever. If such silent, lurking calculi could be discovered and removed many deaths from calculous anuria, much illness and suffering from perinephric abscesses and renal fistulæ and many kidneys gradually undergoing atrophy or disorganisation might be saved by well-timed operation. Unsuspected calculi group themselves into two classes: those which do not excite symptoms and those which cause symptoms which are not referred to the kidney or ureter.

A. Calculi which do not cause symptoms.—I might quote several cases in which a calculus after existing for years has set up perinephric abscess without having previously caused any definite renal symptoms. A calculus may grow silently to such a size as to be felt on palpating the abdomen without causing any subjective symptoms. I have met with three or four such cases. I will epitomise one of them. In May, 1894, I saw a woman, aged twenty-seven years, with Dr. Ford Anderson, who for two or three years had suffered from pain and sense of weakness in her back, more especially in the left side. About four weeks before I saw her she began to pass muco-pus in alkaline urine, and five days before she was seized with violent pain in the left renal region, which lasted many hours, in spite of morphia injections. Following upon this attack were several rigors, a temperature of 105° F., more or less continuous pain in the left side, and some fulness in the left flank. When I saw her she was extremely ill, with a hectic flush on her cheeks, widely dilated pupils, a small, rapid, weak pulse, a furred tongue, and very marked nervous depression and anxiety. She complained of pain over the left kidney, but had never felt pain and was quite unaware of anything wrong in the right kidney. On the *right* side there was a hard irregular swelling plainly to be felt in the loin and through the anterior abdominal parietes. Through an incision in the right semilunar line the *left* kidney was made out to be larger and more globular in form than normal. It was quite impossible to be sure that the enlargement was due to anything other than simple hypertrophy. At the inner and lower border of the *right* kidney was felt a lump, which was obviously a large calculus filling the infundibulum and projecting into the upper part of the ureter. Through an oblique incision in the *right* loin a calculus weighing 830 grains was removed.

It was, I believe, little more than a coincidence that after this operation on her right kidney the patient lost all her pain on her left side. I think the relief she felt was owing to the stone, which was blocking the left ureter, slipping back into the renal pelvis during the movements requisite for the operation, or under the relaxing influence of the anæsthetic. It was plain, for the following reasons, that the pus in the urine, both before and after the nephrolithotomy, must have come from the left kidney: (1) the urine remained unchanged by the operation; (2) the right ureter was completely blocked before the operation by the large stone removed, to which the whole infundibulum was tenaciously adherent; (3) after the operation all the urine secreted by the right kidney escaped through the lumbar wound; (4) there was no pus found about the stone in the right kidney. It is also equally certain that the calculi which were later passed and removed by operation from the left kidney had been the cause of the feverish and nervous as well as of the urinary symptoms, and that I had, so to speak, operated upon the wrong organ. This arose through my following the teaching, to which a good deal of importance was attached by the distinguished operator who originated it, namely, that a stone in one kidney may cause pain to be referred to the opposite kidney, without itself being the seat of pain; and that if the abdominal route is taken we shall be able to avoid operating upon the wrong kidney by finding out by direct palpation in which organ the stone is really situated. In this particular case cœliotomy was not needed to discover the stone in the right kidney; this was done at the bedside. On the other hand, it did not enable me to ascertain that the left kidney contained one large branched calculus and two others of smaller size which I removed at a subsequent operation nine months after the first, as well as a calculus which was passed naturally from the left kidney during convalescence from the nephrolithotomy on the right kidney. The left kidney, with the hand in the abdominal cavity, was felt to be enlarged, more or less globular, and of uniform firmness. It was very carefully palpated for stone, but nothing was felt beyond what was consistent with simple hypertrophy.

Fifteen years ago, in a paper published in the Transactions of the Royal Medical and Chirurgical Society,[5] I called attention to the uncertainty of ascertaining the presence of a calculus by direct palpation of the kidney, either with the hand in the abdominal cavity or after the kidney had been removed from the body. In the Transactions of the Clinical Society of 1887[6] I again referred to the same probability of error. Further experience has convinced me of the fallacy

[3] Medical Times, April 4th, 1885.

[4] Transactions of the American Surgical Association, vol. xii., 1894, p. 113.

[5] Vol. lxviii., p. 75, et seq.

[6] Vol. x., p. 109.

of this mode of examination and I would lay it down as an axiom that the kidney which ought to be first explored is the one on the painful side. I shall refer in my next lecture to a case of calculous anuria in which calculi could be felt through the abdominal wall in the right kidney, but the attacks of pain associated with the anuria were referred to the left kidney. I operated upon the painful side, found a small stone in a large, hypertrophied kidney, and the paroxysms of pain and anuria ceased entirely.

There is not, so far as I know, any case on record in which there is completely satisfactory evidence of symptoms on one side only being caused by a stone in the kidney of the opposite side. The presence of a stone on one side is not proof that the opposite and painful side is not also affected. That the attacks referred to one side have ceased after operating upon the opposite and painless side is not conclusive. This may be a coincidence and due to the accidental shifting of a calculus in the painful kidney or to some other cause. Of course it may happen that with a great deal of disease on the painful side there may be silent or quiescent disease on the opposite side, and this quiet disease may be so advanced as to cause a fatal issue after operating on the painful side; but this is an entirely different question. In several of the fatal cases in my lists of nephrotomy and nephrectomy for stone, the opposite kidney has been proved, by post-mortem examination to be disorganised by unsuspected calculus. It may be asked, "Is it consistent to reject the theory of transferred or reflected pain, as applied to the opposite kidney, and yet to accept it when applied to the bladder or to the ovary?" Well, I believe it is. I have verified the one and have not seen any proof of the other. I do not attempt a full explanation of this; but I would point out that there are instances of a nerve connexion between parts on the same side of the median line more direct than between similar organs or parts on the opposite sides of the body.

B. Unsuspected calculi with symptoms transferred to other organs.—In renal calculus the symptoms may be referred to the bladder, ovary, or testicle instead of to the kidney. I am constantly seeing cases of renal calculus and other renal diseases which have been under prolonged and repeated treatment for cystitis. Bladders are frequently sounded, irrigated, injected with solutions of silver nitrate, and otherwise actively treated, without apparently the least suspicion that the trouble is due to stone in the kidney. I will mention one very striking instance, in which for nearly ten years all symptoms pointed to the bladder, none to the kidney; but at length a renal calculus was removed and the patient regained perfect health. A married woman, aged thirty-five years, leading an active life and of a physically and mentally healthy constitution, had suffered from very painful micturition, cystitis, and frequent phosphatic concretions in the bladder for two years. All the tried remedies having failed to give relief, a vesico-vaginal fistula was established by operation and the urine was allowed to flow away continually into a urinal. This state of things went on for some years and then the vesico-vaginal fistula was closed. No sooner had this been successfully accomplished than all the old symptoms returned, so that in two or three months the fistula had to be re-established. In this condition the patient passed over nine of the best years of her womanhood. Then some pain and some extra resistance were experienced in the right renal region, and after four or five months' duration I was asked to see her by Dr. Fenton, who had diagnosed right renal calculus. I endorsed this opinion and on May 14th, 1893, I removed a small lozenge-shaped uric acid calculus weighing only 4 gr. through an incision in the convex border of the kidney. The patient made an uninterrupted recovery and when quite convalescent from the nephrolithotomy Dr. Fenton closed the vesico-vaginal fistula. The patient remains well to this day, has perfect control over her urine and, as she expresses it, "finds her life quite a different thing and now well worth living."

C. Unsuspected calculi with high temperature and great psychical disturbance.—This third group of cases is well illustrated by the following, the patient being desperately ill for two or three months with symptoms of a typhoid type, attended with acute but vague pains over the whole body, and with great mental prostration, the illness terminating after the discharge of a few ounces of pus and some renal calculi, presumably from the left kidney. On June 16th, 1893, I saw, with Mr. Ewart of Eastbourne, a man from the East, where he occupied a position requiring great mental and bodily activity. For a few days before sailing for Europe he was not feeling well and on his arrival at Brindisi he was so ill and in such pain when moved that he was screaming while he was carried ashore. With great difficulty and several halts he reached Aix, where he became too ill to go further. His symptoms whilst at Aix were high fever, frequent rigors, and, as he himself described them, excruciating pains all over him. Sometimes the pains were worse at one part, sometimes at another, but there was a slightly marked predominance on the left side of his trunk and left lower limb. His urine was offensive and contained pus. It was suggested that he might have a renal calculus, but there was no indication in which kidney it was. Accompanied by Mr. Ewart he at length reached London, though it once or twice during the journey seemed impossible that he could do so alive. Frequent doses of morphia had to be given to relieve pain. When I saw him on his arrival in London he was emaciated to a marked degree, hectic, and had a high temperature with extreme general hyperæsthesia. He was tender and complained of pains all over him, cried out or groaned when touched; but at one time he would complain most bitterly of a part which at another time seemed free from pain and could be handled without hurting him. He was shockingly depressed, would take no food willingly, and lay always in a lethargic state except when touched or moved, which he often tearfully resented. By his relatives he was seen to be quite changed, his temperament was altered, and his nerve and moral courage were lost. The urine was 1015, turbid, alkaline, very offensive, depositing an abundant whitish sediment, and contained a distinct but not a large amount of pus, many of the pus cells undergoing fatty degeneration. There were neither blood corpuscles, sugar, tube casts, nor tubercle bacilli in the urine. On the following day I examined him under an anæsthetic. Nothing abnormal was detected about his bladder, prostate, or urethra, nor in any part of the abdomen or pelvis. There was no undue fulness or hardness of either kidney to be felt. Dr. Cayley and Dr. Ringer saw him on three or four occasions, but we were unable to come to any definite diagnosis except that there was some focus of suppuration somewhere within range of the genito-urinary organs, but precisely where we were unable to say. On the whole it seemed most likely to be in the left kidney; but with this uncertainty, and in the serious febrile and exhausted state of the patient, I was unwilling to urge an operation, which the physicians by no means encouraged me to do. He improved but little during his stay in London, and on July 15th he was removed to his house in the country. A calculus and pus were passed on Aug. 28th. The after temperature was 103° F., and he had a rigor on the previous day. After this he much improved. On Oct. 6th some more pus and four stones were passed and he then got quite well. He returned to his duties in the East on Oct. 20th, 1893. He was seen by Mr. Ewart in August, 1897, in excellent health and quite his natural self.

It is a question whether the nervous and mental phenomena without fever are a peculiar form of uræmic brain symptoms or whether the renal disease, like any other serious disease, is a direct cause of the psychical disturbance. The character of the disturbance is especially one of depression—melancholia, stupor, and nervous apprehension of danger being the most frequent forms. Psychical disturbance has been often noted in Bright's and other renal diseases. I have seen it in advanced lardaceous disease without any other affection of the kidney. But in these disorders other unmistakeable uræmic symptoms existed which have not been present in the calculous cases to which I am now alluding.

QUIESCENT CALCULUS

is little less dangerous to its possessor than the unsuspected stone. It is often said, "the stone may settle down and become imbedded in the kidney or it may pass naturally, and then there will be no further trouble." But often this is not so. One of my objects in this lecture is to show that neither the one nor the other of these events can be looked forward to with perfect equanimity, and that in every case in which a stone is believed or known to be present the best course is to explore the kidney and remove the stone. We ought not to close our eyes to the possibility of sudden danger arising from a hitherto quiescent calculus or from one giving only slight and occasional reminders of its existence. If I am rightly informed, the insurance offices are wise enough not to do so, nor should the surgeon.

MIGRATORY CALCULI.

Lastly, I want to show the possible and actual dangers of leaving a calculus to make its own way out of the urinary passages. In this connexion let me ask what would be thought of a surgeon who advised a patient with a stone in his bladder to wait a few months and see if it would pass through the urethra naturally on the ground that it was only a little stone and therefore would be able to make its way perhaps without, perhaps by dint of, stretching; that the process might be a painful one, or might not; that when once the calculus got into the passage the force of the pressure of urine behind would be almost sure to drive it onwards, but that if it did not do so, or alarming symptoms due either to the over-distension of the organs behind or to the sloughing of the part of the tube in which the calculus was impacted, then, and then only, resort should be had to an operation. This is precisely the line of argument daily acted upon in the case of renal calculus. And why? Not because less damage to the kidney will result from the obstruction in the ureter—on the contrary, the serious effect of a blocked ureter is much earlier and much more rapid in its progress; not because the suffering from renal calculus is less than from vesical calculus; not because extravasation of urine never occurs from obstructed ureter or renal pelvis, for witness the perinephric and perireteral abscesses and fistulæ, but because of the supposed risks to life of operation on the kidney. This reason is really no longer tenable. No operation practised for vesical calculus has a lower mortality than nephrolithotomy. For years I made it a practice in cases in which the symptoms were slight and of only recent occurrence to treat the patients for a time on the expectant plan. I have several specimens passed in this way; they are the emblems of what ought to be very largely an obsolete treatment.

Summary.—The conclusions at which I have arrived are the following.

1. That the aim of the surgical treatment of renal calculus should be to extend the application of nephrolithotomy and thereby restrict the necessity of nephrotomy and nephrectomy.

2. That more frequently than not the failure to find a stone is not in reality a failure of treatment, because there are so many curable morbid conditions which mimic renal calculus and which are discoverable only by exploration.

3. That the theory that a stone in one kidney, whether that kidney is itself painful or not, reflects or transmits pain to the opposite kidney, is quite unproven; that it is a dangerous theory calculated to lead to very erroneous practice and that the surgical principle with regard to exploratory operations should be that with pain, paroxysmal or continuous, on one side only the kidney on the painful side should be explored.

4. That nephrectomy for calculous conditions is very rarely called for and should be done only in most exceptional cases. Nephrotomy for calculous pyonephrosis is the proper operation—at any rate as a primary operation—because of the frequency of double calculous disease. Experience has shown that kidneys from which stones weighing 830 gr. and 1300 gr. have been removed are functionally sufficient to maintain life during the blocking of the ureter and the suspension of the function of the kidney of the opposite side.

5. That nephrectomy whilst the opposite organ is occupied by calculus is fraught with very great danger to life; whereas nephrectomy after the opposite kidney has been freed from stone will probably be followed by recovery from the operation and possibly by very good health for years afterwards.

6. That when renal calculus causes reflected or transferred vesical or ovarian pain the removal of the calculus will be followed by complete cure of the bladder or ovarian symptoms.

7. That in some cases renal calculous conditions are attended by very remarkable nervous symptoms, sometimes with sometimes without high temperature, and that information as to the cause of these symptoms is needed.

8. That unsuspected renal calculi are a source of very real danger to their possessors, and when, whether by accident or by the systematic examination of the urine, we have cause to suspect the presence of a calculus we should recommend its immediate removal regardless of the fact that it is not causing renal or transferred pain.

9. That quiescent calculus is as dangerous to the individual as unsuspected calculus and ought to be removed by operation.

10. That the hitherto accepted teaching that a renal calculus, if causing only mild symptoms or attacks of renal colic of only recent occurrence, should be treated on the expectant plan ought to be discarded as unsound in theory and dangerous in practice.

11. That the same principle should be applied to renal calculus which has long been the rule in regard to vesical calculus—namely, when suspected it should be searched for; when known to exist removed, without waiting in the hope that it may become encysted or spontaneously expelled.

12. That the very low mortality of nephrolithotomy puts this operation upon the same footing for renal calculus as lithotrity in the most experienced hands for vesical calculus.

A SHORT ACCOUNT OF THE MIDDLESBROUGH SMALL-POX EPIDEMIC—1897-98.

BY CHARLES V. DINGLE, M.D., B.S., B.HY. DURH.,
MEDICAL OFFICER OF HEALTH FOR MIDDLESBROUGH PRO TEMPORE.

UP to and including March 31st, 1898, there had been 1200 cases of small-pox notified during the epidemic at Middlesbrough. The first case was notified on Nov. 22nd, 1897. The origin of this case is somewhat obscure; it was supposed at the time to have been contracted at a wild beast show which visited Middlesbrough on Nov. 10th and remained two days, but on further inquiry I have been able to elicit the fact that this person and a friend visited the show together on the evening of the 11th; they were both afterwards attacked by small-pox, the case of the friend not being notified. Both say they felt ill on the night they visited the show. In the case which was notified the patient was removed to the hospital with an unmistakeable small-pox rash on Nov. 22nd—i.e., only eleven days after having been at the show. The patient in the case which was not notified was the wife of a coloured sailor and it is more than probable, although it cannot be definitely proved, that the sailor brought the infection into the town, his wife, sister-in-law, and niece, all living in the same house, and the friend already alluded to, who frequently visited the house, being the first persons to be attacked. This man was in constant contact with the sailors of the port and it has transpired that small-pox was raging in Bilbao and other Spanish ports all last year, there having been no less than 418 deaths from small-pox in Bilbao alone during the year. On an average from two to three vessels enter the port of Middlesbrough every day all the year round from Bilbao and neighbouring ports laden with iron ore, which they discharge at the wharfs in Middlesbrough and at the works on the banks of the river Tees. That cases of small-pox have been imported from Bilbao I know. One sailor left his ship at this port on Feb. 8th last year. He was known to have been about the town and on Feb. 16th was admitted into Sunderland Small-pox Hospital with a fully-developed rash of at least a week's duration, showing that he had small-pox at the time he was in this town.

There was also another source by which the infection may have been brought into the town. On Nov. 2nd, 1897, there arrived in Middlesbrough about 800 navvies gathered together from all parts of the country. They were engaged laying down new tram-lines and were working for a period of nearly three months; no cases have been directly traced to them. After Dec. 4th no cases were notified until Dec. 27th, so that it looked as if the first group of cases had been stamped out. On looking for the cause of the second outbreak I found again that one of the first two families to be attacked had been in close contact with the sailors of the port, the child who was attacked having gone amongst the ships and sailors selling small articles. On Dec. 31st a wake was held over the body of an Irish Roman Catholic who lived close to the infected house from which a child had been removed on the 28th. This case was unrecognised until after death, but there is no doubt that the cause of death was small-pox of a very virulent nature. Dozens of people attended this wake and the rapid extension of the outbreak

can be clearly traced as the result of this wholesale infection. On Feb. 6th, 1898, 37 cases were notified and 75 cases on the 8th, being the greatest number notified in any one day during the epidemic. From this date the epidemic has run the usual course, there being periodical recrudescences, in this instance each succeeding outbreak only averaging half the number of cases in the previous one. The epidemic is not ceasing with the suddenness of the Gloucester outbreak, but is, on the other hand, dying a hard death.

Before the epidemic the sanitary authorities of Middlesbrough had a provision of 14 beds and 2 cots for small-pox cases alone. These were in a separate block but within the same grounds as the block for other fever cases. The main block contained 46 beds used for scarlet fever and typhoid fever. There was also another small isolation block. As soon as it was seen that the provision made for small-pox cases was inadequate the sanitary and sanatorium committee ordered a Humphrey's corrugated iron block, capable of providing 20 beds; the erection of this was immediately proceeded with. In the meanwhile 4 tents were obtained and pitched, but owing to the site chosen for them being close to that on which the workmen were engaged in erecting the Humphrey's building it was not found possible to utilise them, the workmen refusing to work on the buildings so long as there were patients in these tents. Up to Feb. 6th it had been found possible to isolate all the cases, but owing to the sudden increase on that day and on the 8th the accommodation was insufficient for all the cases and only the worst, as far as surroundings and severity, could be provided for, the rest remaining at their homes. The work of erecting buildings was pushed on as rapidly as possible and by March 3rd the authorities got so well ahead with their work of providing accommodation that it was possible to once more isolate every case as it occurred and also to take in as many of the cases which had been left in the town as could then be persuaded to be removed. Finally provision was made for 322 beds, the greatest number ever occupied at one time being 578. The blocks of buildings are divided into three sections, facetiously named by the patients, "Dawson City," "Klondyke," and "Kimberley." The first section consists of six of Humphrey's iron buildings on brick foundations, the second section of ten wooden buildings, and the third section of six wooden buildings, all likewise on brick foundations. The permanent hospital and the block originally built for small-pox have been used for administration purposes alone. Besides the above there are a permanent brick-built disinfecting-house containing a steam Washington Lyon's disinfector, a small temporary dwelling-house built of corrugated iron, in which two resident medical assistants reside as well as a resident clergyman, and properly constructed kitchens, laundries, discharging block, and storehouses, &c.

Statistics.—At present it is not possible to use the whole of the cases for the purpose of statistics, so I have taken the first 1200 cases—that is, all that had been notified up to April 1st. It is possible that there may still be some more deaths to take place amongst these cases, but there cannot be so many as to materially alter the value of the following tables. In 1897 the estimated population of Middlesbrough was 89,246; it is probably now 90,000. At the beginning of the epidemic a vaccination census was taken by the guardians; the enumerated population, that is, those who were found at home at the time the census was being taken, is given at 69,525, or roughly about 20,000 less than the estimated population. Of the above 68,219 were found to have been primarily vaccinated, 1306 were unvaccinated, and 14,163 had been revaccinated at some period or other of their lives. Of children under fourteen years of age 653 were reported to be unvaccinated. As regards primary vaccination this shows Middlesbrough to be a well-vaccinated town, but the same cannot be said regarding its revaccination. It can reasonably be supposed that the 20,000 not enumerated would be vaccinated in about the same proportions as the above. There are said to be nearly 40,000 children attending the various schools of the district. Taking the 1200 cases attacked, we find they are divided into 1028 who are vaccinated and 172 who are unvaccinated. It is not strictly accurate to work from the enumerated population given by the guardians, so I will take the percentages from the estimated population of nearly 90,000. If these, as I have stated above is most probable, are vaccinated in the same proportion as the enumerated population we have 87,844 vaccinated and 1682 unvaccinated persons in Middlesbrough.[1] We now see that the attack-rate, 172 cases, amongst the unvaccinated is equal to 10·2 per cent. of the population, whereas the attack-rate, 1028, amongst the vaccinated is only equal to 1·1 per cent. of the total population.

I will next give the fatality-rate for cases attacked. Up to the present time there have been 166 deaths amongst the 1200 cases, that is, 13·8 per cent. of the cases. This is not the death-rate for the whole epidemic, but only represents that for a definite period; nevertheless, as it is not likely that there will now be any more deaths occurring in this group of cases it gives a very accurate knowledge of the proportion of deaths between vaccinated and unvaccinated cases. Of the 166 deaths 79 occurred amongst the unvaccinated cases or cases of doubtful vaccination—that is, cases which are said to have been vaccinated but on whom no marks of the vaccination are visible. This is equal to a fatality-rate of 45·93 per cent. as compared with 87 deaths amongst the vaccinated persons attacked, equal to a fatality-rate of 8·46 per cent. The following table gives the age periods of all the cases, also for the vaccinated and unvaccinated, separately, together with the deaths in each of the latter.

Age periods.	Total cases.	Vaccinated.	Died.	Unvaccinated.	Died.
Under 5 years	29	9	1	20	10
5 years and under 10 years ...	65	32	0	33	14
10 ,, ,, 15 ,, ...	117	99	2	18	3
15 ,, ,, 25 ,, ...	409	384	19	25	13
25 ,, ,, 60 ,, ...	574	501	64	73	38
60 years and over	6	3	1	3	1
Totals	1200	1028	87	172	79

An examination of this table shows the protection afforded by vaccination to life at all age periods. Taking the children under ten years of age we find 94 cases; of these 41 were vaccinated and 53 were unvaccinated, but when we look at the death column we find that out of the 41 vaccinated children only 1 died, whereas of the unvaccinated 24 died.

The following table refers to the revaccinated cases. Out of 1200 cases 56 had been revaccinated at one period or another of their lives. I give the age periods of these cases and the date of revaccination in days before the attack. Of these one died, revaccinated 13 years ago, aged thirty years. Up to March 31st this was the only death in a revaccinated person:—

Age periods.	Number of days revaccinated before attack.														Total number of cases.
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	Over 14 days.	
Under 5 years	—	—	—	—	—	—	—	—	—	—	—	—	—	—	1*	1
5 years and under 10 years	—	—	—	—	—	—	—	—	—	—	—	—	1	—	—	1
10 years and under 15 years	—	—	—	1	1	—	—	—	—	—	2	—	1	1	2†	8
15 years and under 25 years	—	—	—	—	1	1	1	2	3	4	2	2	—	1	3‡	20
25 years and under 60 years	2	—	—	1	—	2	2	1	2	2	1	1	2	3	6§	25
60 and over	—	—	—	—	—	—	—	—	—	—	1	—	—	—	—	1

The following means have been taken for dealing with the epidemic. I have already given a short account of the accommodation provided at the sanatorium. The difficulty experienced was not that the authorities did not fully realise their position; it arose from the impossibility to procure sufficient workmen. The duty of seeing to the erection of the temporary hospitals was in the hands of a sub-committee and when the report of their work comes to be published it will be seen that they carried out their duties to the smallest detail in a manner very rarely, if ever, accomplished before. Not only is there a perfect system of drainage to each ward, but also systems of hot and cold water and gas are laid on. The wards are bright and cheerful, being decorated internally with plants and pictures. The food is excellent, well cooked, and plentiful, and I have heard nothing but praise from all the patients who have been discharged as cured. Isolation has been very efficiently carried out; of the 1200 cases 1078 have been removed to the hospital and treated there. Disinfection by means of SO^2 cylinders of the infected houses was performed as soon as ever the patient was removed. The bedding and clothes of the patients were removed with them and passed through a Washington Lyon's disinfector. Mattresses and beds were also passed through the disinfector, but in many cases, if dirty, were destroyed by burning.

Vaccination has been carried out in various ways; two public stations were opened at which the public vaccinator and his assistants were present all day to vaccinate any presenting themselves free of cost. When the numbers attending these stations began to decline domiciliary vaccination was undertaken by the guardians; the town was divided into twelve districts, and each district was canvassed by a medical man attended by a clerk. Since then the corporation have provided free lymph to the medical men of the town and anyone wishing to be vaccinated can be attended to by their own medical attendant free of charge, the medical man being paid by the guardians for every successful vaccination. Every infected house is also visited and vaccination offered to the inmates.

Middlesbrough.

CLINICAL REMARKS ON STRICTURE OF THE URETHRA.

BY REGINALD HARRISON, F.R.C.S. ENG.,
SURGEON TO ST. PETER'S HOSPITAL.

THE following classification of strictures is one which may be conveniently used for clinical purposes. First, those amenable to some form of dilatation; second, those found to be unadapted for such treatment and where other measures should be considered; and third, those which may have been regarded as impassable strictures. I shall limit my remarks to questions arising under these three headings.

The first class includes by far the greatest number and all strictures in their early stages. When this process of treatment proceeds satisfactorily, as it usually does, the patient is soon able to undertake the management of his own case after he has been instructed in the use of the appropriate instrument. For whatever is done in the way of treatment by dilatation or otherwise in the majority of advanced forms of urethral obstruction the patient can seldom hope to entirely dispense with the passing of a bougie. When a person who is suffering from symptoms which may indicate stricture presents himself for the first time, much care is required in exploring his urethra with a catheter or bougie. It is very easy to spoil a stricture and so lose the way through it. Thus future access to the bladder may be rendered rather more than less difficult. On making an examination of this kind our object should be to ascertain, without causing pain or bleeding if possible, (1) the presence and position of the obstruction, and (2) the degree of contraction which has been arrived at. It is undesirable to endeavour to pass an instrument into the bladder without knowing all this beforehand, otherwise we may easily select one too large for the purpose and so in the first attempt do more harm than good. The thinnest end of the wedge must first be inserted and then the dimensions of the contraction can be readily and accurately gauged. In view of giving effect to these points I described fifteen years ago[1] a flexible conical bougie or dilator which, so far as my experience of it goes, has superseded most instruments of this kind and has been the means of considerably reducing the number of what are called impassable strictures. These instruments are used both for locating and measuring all kinds and degrees of urethral stricture. They are about 20 in. long, commencing with a fine probe-ended extremity, which gradually expands in the opposite direction. They are made in different sizes and are rendered extremely flexible when placed in warm water for a few minutes if necessary before using them. In this way they will readily coil up within the bladder. I much prefer the French make (Lassère's); I find them useful, not only for the purposes I have mentioned, but for smoothing out a rough urethra and making the access to a stricture funnel-shaped so that it may be easily entered by almost any other instrument. The late Mr. Lund of Manchester christened them "whips" when I first showed them and he adopted them, and they have since always gone by this name. Bangs' filiform bougies, made on the same principle of the finest whalebone, are applicable to even more contracted forms of obstruction, such, for instance, as the eccentric pin-hole strictures which are occasionally met with. They may also often be used with advantage as pilots for the "whips." I can strongly recommend both of these instruments to practitioners who are liable to meet with stricture cases and have not hitherto given them a trial. Either of them will do duty in an emergency in relieving a retention of urine in the absence of a catheter by at once dilating the stricture to almost any extent by a single introduction of the instrument. On its withdrawal the patient is usually able to empty his bladder immediately by his own efforts. I have frequently used them in this way with prompt relief. I think they should be more generally known. No force can be exercised by them, otherwise they will double up and the object be defeated.

Passing to the second class of cases, which includes strictures found on trial to be unadapted for any form of dilatation, when for any reason a large amount of scar tissue has been imported into a stricture—as, for instance, in obstructions following wounds and injuries of the urethra—it may be found impossible to sufficiently dilate the contraction which follows. This may proceed from some difficulty in connexion with the access or entrance to the stricture, as when damage has been done to the interior of the urethra, from the inherent contractility of the tissue composing the obstruction, or from certain constitutional disturbances following attempts at dilatation even of the gentlest and most gradual kind. Let me briefly illustrate these three conditions.

CASE 1.—A man, aged forty-two years, saw me in 1890 under the following circumstances. He was a great traveller, and though he had a slight stricture for which he occasionally used a bougie himself he was not inconvenienced by it. About a year before I saw him he had had sudden retention of urine following a chill when he was in a remote part of Australia and there had been much difficulty and bleeding in relieving him with a metal catheter. Since this happened he had never felt certain whether he would be able to pass his bougie. Sometimes it would enter and at others it

[1] THE LANCET, Feb. 3rd, 1883.

would not. Though he continued to pass his urine in a fair stream this uncertainty unnerved him and prevented him travelling abroad as an explorer as he had been accustomed to do. In every other respect he was in excellent health. I examined him and found a short cul-de-sac, which was probably the remains of a false passage below the line of his stricture and which occasionally caught the tip of his bougie and prevented it entering the stricture above. There was, in fact, a sort of valve arrangement. I performed an internal urethrotomy for him and divided the floor of the stricture, so, as it were, throwing the siding into the main line. He has since had no difficulty whatever and has resumed his explorations in various parts of the world.

CASE 2.—This was a man, thirty years of age, who in 1893 damaged his deep urethra by being thrown forward on to the pommel of his saddle. A stricture followed which proved most contractile. There was no difficulty in dilating it up to a No. 12 bougie, but this was invariably followed by an attack of retention of urine in the course of a few hours. It was all the same whatever degree of dilatation was attempted. I advised an internal urethrotomy to be performed. A splice of new tissue was thus introduced and he has since been free from all further inconvenience beyond occasionally passing a full-sized bougie for himself.

CASE 3.—The patient was a man, aged fifty years, who had spent much time in Africa and had contracted several malarial fevers. One or other of these was invariably roused up when he passed his bougie, in spite of large doses of quinine taken as a preventive. The fever necessitated his spending two or three days in bed on each occasion. The stricture was a very contractile one, and though the instrument passed tolerably easily on its withdrawal it was firmly gripped and then the constitutional symptoms followed. I performed an internal urethrotomy for him after well sterilising his urine previously and taking other antiseptic precautions (as I shall presently note). The patient has since had no further trouble of this kind. It is curious to observe the effect of tension, and its removal, relative to the production and prevention of urethral fever and the other fevers which it resembles.

In cases such as these and the like we may do immediate and permanent good to strictures which will not yield to dilatation alone, and thus prevent the bad effects of back pressure gradually extending to the bladder and kidneys above, by introducing a splice of new material into the contracted portion of the canal, much on the same principle as we should expand a tight garment. For these purposes I usually select Maisonneuve's instrument. It consists of a fine pilot and director upon which a small triangular knife dulled at the apex runs. It can thus only divide the contracted portion or portions of the canal and this it does by a clean linear longitudinal incision corresponding in depth with the size of the blade. As healing takes place, under the occasional use of a bougie a splice or interval of new tissue is introduced between the lips of the incision and thus the calibre of the canal may be considerably increased in a short time. For forty-eight hours or so before this is done it is well to sterilise the urine with some boric acid taken by the mouth in small doses or with what I have found still better, boracite. The former sometimes produces indigestion whilst the latter is both pleasant and reliable. The filiform pilot is then passed through the stricture into the bladder, the fine metal director following it. The urethrotome is next run along the groove in the latter and the stricture or strictures are divided from before backwards. Care should be taken not to run the blade further than the last point of contraction, so as to avoid touching any fibres of the bladder sphincter. The latter is unnecessary and may cause some bleeding. To make sure that all stricture fibres are severed and a clear interval is provided between the lips of the incision thus made a short series of Lister's metal bulbous bougies (10 to 15, English gauge) should be successively passed before the patient recovers from the anæsthetic. The ordinary round-ended bougies are not suitable for this purpose, as they may catch in the lips of the wound. It is a matter of much importance to secure a perfectly smooth, soft scar. All metal instruments for use in connexion with a strictured urethra should be bulbous or olive-headed. The bladder is then emptied of any urine it may contain and washed out with a solution of perchloride of mercury (1 in 6000) until the lotion returns quite clear. An ounce or so of the solution is left behind in the bladder so that the first portion of the urine voluntarily passed is sterilised. This completes an operation which need not occupy more than a few minutes. Carbolised vaseline (three grains to two ounces) is used for the instruments. I rarely tie a catheter in the bladder unless—as sometimes happens—a chronic stricture has induced an atonic bladder, when a soft rubber catheter may be retained for forty-eight hours or so, otherwise we may have high temperatures until the viscus is artificially emptied. With these antiseptic precautions there is seldom any marked degree of urinary fever. On the fourth or fifth day after a whip bougie is generally passed and the patient is instructed in the use of a suitable instrument. For many years Maisonneuve's operation has commended itself to me on the grounds of its simplicity, its adaptability to the most contracted forms of stricture, and the benign character of the scar tissue which usually results. I have therefore referred to some details to which I have learnt to attach considerable importance. The extension of the antiseptic principle to these operations has in all respects greatly benefited them.

Still more rarely there are cases of stricture met with where neither dilatation nor internal urethrotomy will cover the ground the contraction occupies. Instances occur when, by reason of contraction, abscess, and fistula, the perineum and urethral wall become matted together and converted into a hard mass of dense warty-looking tissue which can be only successfully dealt with by some form of perineal section. This, however, though the cases may be comparatively few, is a subject of itself and requires a consideration which cannot be included within the limits of these remarks. It must be reserved for another occasion.

I will therefore pass on to the third division of my classification—patients who present themselves for treatment on the ground that they are suffering from an impassable stricture. In my earlier days I was much impressed by the teaching of Syme, endorsed by Bickersteth of Liverpool in his practice, to the effect that such a term as "impassable" could only be used in a somewhat relative sense and was inapplicable unless the canal was structurally or, if I may use the term, hermetically closed, as, for instance, when a urinary fistula coexisted. Syme thus refers to this point: "There is nothing of more consequence in the treatment of stricture than knowledge of the fact that this alleged impermeability has no real existence except in those rare exceptional cases where the urethra has been divided by violence and allowed to cicatrise with obliteration of the passage beyond the opening at the seat of injury. It is obvious, indeed, that if the urine is permitted to pass, no matter in how small a stream, there must be room for the introduction of an instrument provided it be sufficiently small and properly guided."[2] This is a high ideal to take and to attempt to follow, but it puts into prominence the first principle associated with the treatment of urethral stricture whatever form it may assume. Though we may fail to attain it, the possibility of doing so in a legitimate and scientific manner should never be lost sight of. If such a conclusion as this could have been arrived at in the time of Syme how much more so is it within our reach in the present day after what has been done in improving the construction of all kinds of instruments used for this purpose. Though much patience and tact is often required in obtaining access to the bladder through a contracted stricture, failure, I believe, need now but rarely occur. Nor is the attainment of this a matter of indifference relative merely to the adoption of one out of two eligible courses. Experience shows that as there are strictures which need not be cut merely because they may seem in the first instance to be impassable so far as a bougie is concerned, so are there strictures which though passable in this sense are yet found to need cutting. No sufficient answer can be given to the important question that is thus raised until a stricture has been fully explored and this, I believe, can be generally done. For an impassable stricture I do not think there can be any better alternative than the one associated with the name of Mr. Wheelhouse, where the contraction is sought for by opening the perineum. It would, however, not be difficult to find many surgeons largely engaged in operative work who have never availed themselves of this proceeding on the ground that a stricture had resisted all legitimate efforts to enter the bladder along the urethra.

Lower Berkeley-street, W.

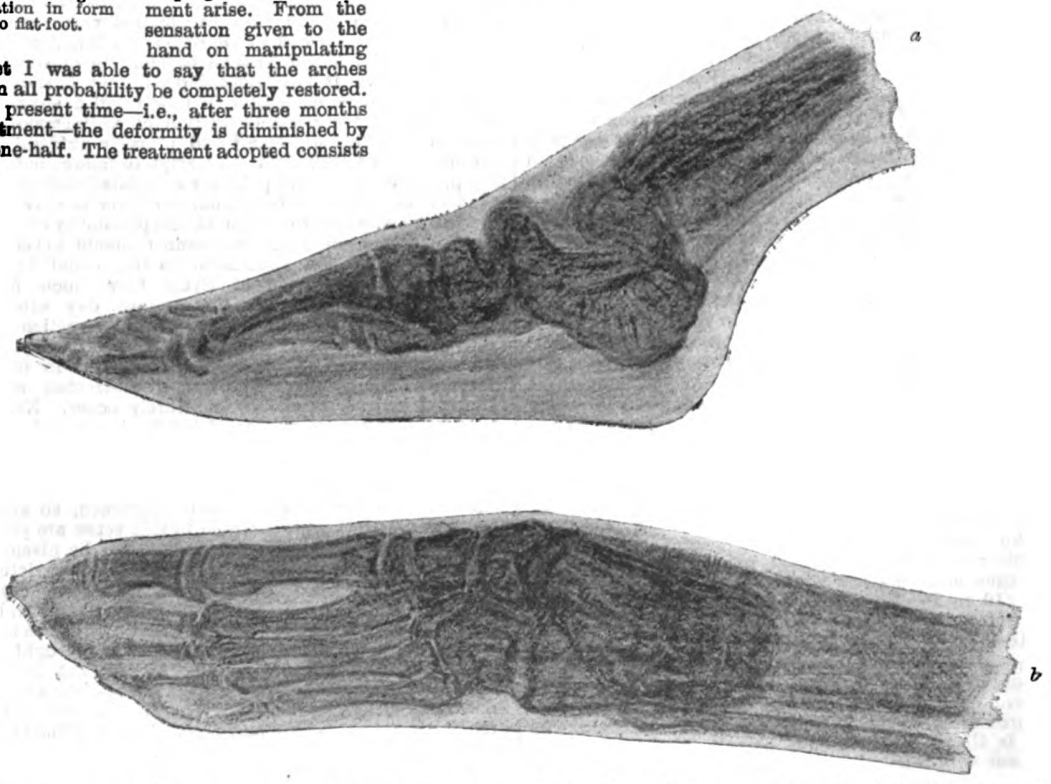
[2] On Stricture of the Urethra, second edition, 1855.

REMARKS ON THE ANATOMY AND TREATMENT OF FLAT-FOOT.

BY J. JACKSON CLARKE, M.B. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON AT THE NORTH-WEST LONDON AND CITY ORTHOPÆDIC HOSPITALS.

JUST as long narrow backs are the most likely to become over-curved from weight acting between the two extremities of the spine, long narrow feet are also the most likely to become flattened from pressure on the highest parts of the arches. Some months ago a little girl, aged ten years, came under my care for lameness and painful feet. For the age and size of the patient the feet were remarkably long; they also showed an advanced condition of flat-foot, the whole of the inner border of the foot touching the ground when the patient stood up. The foot, naturally long, was still further lengthened by the sinking of the longitudinal arches. The footprint, reproduced on a reduced scale in Fig. 1, measured $8\frac{3}{10}$ in. from front to back. Both feet were similarly altered in form and since they showed the condition uncomplicated by hallux valgus, &c., I thought radiographs would be useful in demonstrating the exact changes in the relative position of the bones. The radiographs reproduced on a smaller scale in Fig. 2 were made for me by Messrs. Coxeter, the patient sitting down with the sole of the left foot placed flat on the plate whilst that of the right rested on its outer edge.

FIG. 1.



Footprint showing the alteration in form due to flat-foot.

Here, then, is a common case of static flat-foot of severe degree; the questions of prognosis and treatment arise. From the sensation given to the hand on manipulating the feet I was able to say that the arches could in all probability be completely restored. At the present time—i.e., after three months of treatment—the deformity is diminished by about one-half. The treatment adopted consists in wearing boots properly shaped—i.e., having soles of the same outline as the plate shown in Fig. 3 *b*—and furnished with pads of vulcanised rubber so formed that their highest part falls in front of the transverse tarsal joints. In addition to this an outside leg iron jointed at the ankle and supported by an inside T-strap has been applied in this case. Even for severe cases in hospital practice I find this method rarely fails. Manual wrenchings and douchings are also helpful and as soon as sufficient improvement has been obtained suitable exercises may be begun. Some surgeons would appear to recommend that all cases of flat-foot should be treated by exercises alone. Doubtless three exercises—(1) rising on tip-toe a definite number of times, the toes being inclined inwards; (2) adduction of the foot, repeated several times; and (3) walking for a short time daily on the outer border of the foot—are all of service and in suitable cases may alone suffice, but they are not to be used indiscriminately, as the following instance will show. A boy, aged twelve years, came to me at the North-West London Hospital with marked flat-foot on the left side, the right foot being normal. He was ordered a pad, &c., for the left foot and was carefully instructed to rest save for five minutes twice a day when he was to do the tip-toe exercise. A week later he returned with the right foot pronouncedly flat. Flat-foot thus rapidly developed deserves to be named *acute* and is much more common than is supposed. In this instance acute flat-foot occurred whilst one of the recognised exercises was being carried out. On manipulating the right foot I found it readily reducible to the normal shape, causing but little pain to the patient. After bandaging the foot in an over-corrected position I advised a week's rest in bed and the subsequent use of a rubber pad and leg iron.

Another form of flat-foot that often demands complete rest for a time is that observed in active rickets. Every case requires its own management and also the management of *complications*, of which hallux valgus and hammer-toe are the commonest. As an instance of a method of treatment found to be successful in these conditions I may mention the case of a girl, aged thirteen years, the condition of whose right foot before treatment is shown in Fig. 3 *a*. There are

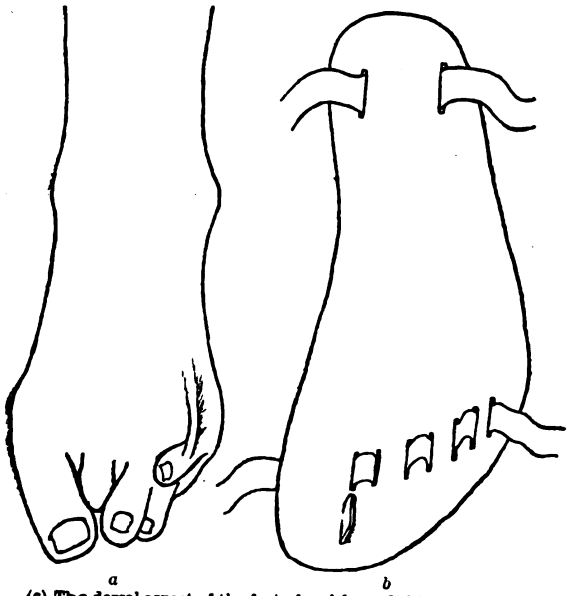


FIG. 2.

(*a*) Radiograph of the left foot seen sideways, showing that the scaphoid is displaced downwards from the head of the astragalus and on the outer side of the foot the cuboid is also displaced downwards. (*b*) Radiograph of the right foot showing the oblique position of the astragalus and some alteration in the shape of its head.

hallux valgus and hammer-toe as well as a not uncommon displacement of the little toe. For this patient I ordered a metal plate cut the same shape as the sole of the boot ought to be, only smaller, with a toe-post and slots for a soft narrow bandage to hold the toes in their proper position. The tense extensor tendon of the little toe was divided subcutaneously. The foot with the plate applied goes easily into a boot of the proper size for the patient, whose toes now, after two months of treatment, are quite normally disposed when the plate is removed. Hallux valgus and hammer-toe are not always so readily remedied as this. In the former condition I have had to open the metatarso-phalangeal joint and trim the head of the metatarsal bone; in hammer-toe the lateral and anterior ligaments of the first inter-phalangeal joint usually require division. In every case careful after-treatment is required.

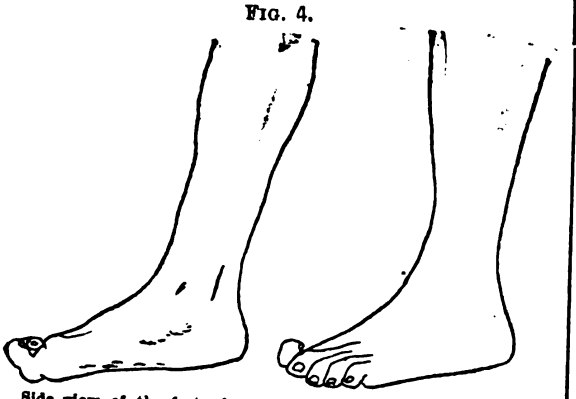

FIG. 3.

(a) The dorsal aspect of the foot of a girl, aged thirteen years, showing hallux valgus and hammer-toe. (b) The metal sole-plate used in the treatment of this case.

The most refractory form of flat-foot is that due to osteo-arthritis or to chronic rheumatism. In such cases, as in severe rachitic cases, the bones become deformed and there may be considerable spasm of muscles. In the case of a man, aged thirty years, who was invalided out of the army on account of the lameness caused by his rheumatism, this

FIG. 4.

Side view of the feet of a man, aged thirty years, showing deformity of the great toes, &c.

condition was present to a marked degree. He is subject to attacks of iritis. The right foot is flat and rigid and the calf muscles of the right side are considerably wasted. On both sides the great toes are curiously bent (over-extended), as shown in Fig. 4. Even in such cases by patient treatment much improvement can be obtained.

Old Cavendish-street, W.

A CASE OF PURULENT PERICARDITIS AND DOUBLE EMPYEMA; OPERATION; DEATH.

BY R. SEVESTRE, M.D. CANTAB.

A MAN, aged twenty-two years, was admitted into Addenbrooke's Hospital, Cambridge, on May 12th, 1897, under the care of Professor Bradbury, who has kindly given me permission to publish the case. On May 7th, 1897, the patient shivered and complained of pain in the left side of his chest; soon after cough came on. On admission on May 12th his face wore a distressed expression and there was a herpetic eruption about the alæ nasi and the right angle of the mouth. The tongue was furred. The pulse was 112, irregular in time and volume. The temperature was 101·8° F. The respirations were 56, being interrupted frequently by a short cough with the expectoration of thick, mucoid, rusty sputum which was found to contain pneumococci. The physical signs in the chest were as follows. Movement was diminished on the left side with vocal vibrations absent in the lateral region and at the base of the left lung. The percussion note was dull below the middle of the left scapula and extended into the lateral region and in this area the respiratory sounds were feeble and bronchial in character; on the right side the breath sounds were exaggerated and some moist sounds were present. The apex beat was not definitely localised, but pulsation could be felt in the fourth left interspace. The cardiac area of dulness was not observed to be increased; the sounds were clear but distant. No friction was detected. Nothing abnormal was detected about the abdomen or limbs. The urine had a specific gravity of 1030 and contained a trace of albumin. The case was diagnosed as one of pneumonia. On May 15th the patient complained of pain in the right lateral region and pleuritic friction could be heard. On the 18th he was restless, complaining much of cough, with great difficulty in expectorating a small quantity of thick purulent sputum. An exploring needle had been passed through the chest wall on the 17th in the seventh left interspace in the post-axillary line, as the physical signs suggested fluid in the left pleural cavity; the result, however, was negative. The apex beat of the heart could be felt with difficulty in the fifth left interspace in the nipple line; the right limit of cardiac dulness extended an inch beyond the right border of the sternum; the upper limit was in the third interspace; the sounds were distant and heard with difficulty. The pulse was irregular in time and volume. On the 24th the patient for several days had been lying persistently on his left side; an attempt to assume any other position caused him great distress. His face wore an anxious expression, was pale and inclined to be cyanosed, this becoming marked after an attack of coughing. The head and extremities were cold and covered with perspiration. Sleep was only obtained in snatches owing to paroxysms of cough. He was sensible when spoken to, but rambled very much when left to himself. His temperature had been erratic, showing a tendency to be higher in the evening than in the morning, but it had not been over 101° for several days. The physical signs in the left lung had not materially altered; over the base of the right lung the percussion note was dull and the breath sounds were much impaired. An exploring needle was passed through the chest wall in the left lateral region and a syringeful of pus was withdrawn; this seemed to relieve him; an attempt at aspiration failed, however, to withdraw any more fluid. On the 25th the general condition of the patient was much worse. Perspiration covered the face and extremities, which were cold and cyanosed. The respirations were rapid and shallow. The pulse varied at times, running barely perceptible and not to be counted. Pitting was obtained over the sternum. No pulsation could be felt over the cardiac area. The right limit of the cardiac dulness was an inch from the right nipple; the upper limit was at the upper border of the second left rib, and on the left side it was continuous with that over the lung. The sounds were heard with difficulty. As the patient's condition was rapidly becoming more serious Professor Bradbury, after consultation with Professor Allbutt, decided to aspirate the pericardium. A hypodermic needle was passed through the chest wall at a spot 1 in. from

the left border of the sternum in the fourth left interspace and pus was withdrawn; the needle of a Potain's aspirator was then passed through the same spot and 23 oz of sweet creamy pus were withdrawn; on bacteriological examination this proved to be almost a pure culture of pneumococci. The effect was extraordinary as the pus came away; the cyanosis and perspiration disappeared entirely, the pulse at the wrist improved, the respirations became deeper and less frequent, and the patient lay with comfort on his back. The apex beat was felt in the fifth space in the nipple line, the cardiac sounds were distinct and clear, and friction synchronous with the heart's beat could be heard along the upper border of the altered cardiac dulness which was now at the lower border of the third left rib. On the 26th the patient passed a good night. The pulse and respiration had improved. The morning temperature was 98°. With these improved conditions it was decided to open the pericardium. Mr. Byles, after injecting four minims of a 4 per cent. solution of cocaine into the spot where he had aspirated, cut down on to the pericardium; as pulsation could be felt at the bottom of the wound a hypodermic needle was passed in and pure blood was withdrawn; it was decided to do nothing further. On the 28th the face was slightly cyanosed, the patient was inclined to be restless, talking to himself, but answered sensibly when spoken to. The respirations were 32. The cough was troublesome with the expectoration of thick muco-purulent sputum. The pulse was 148, soft, and irregular in time and volume. On the 29th his condition was evidently grave. His face had a drawn, cyanosed look and was covered with perspiration. The respirations were 60 and the pulse was 128, very feeble, not "paradox." The temperature was erratic, with a rise in the evening. No cardiac impulse could be felt; the cardiac dulness had increased almost to the extent it was before aspiration. The sounds were muffled. For the last few days he had complained of pain in the epigastrium. The liver dulness was increased downwards. As it seemed clear that the pericardium had refilled Mr. Byles opened the wound in the fourth left interspace, and after pushing a director through the pericardium pus escaped. He then increased the opening and put in a drainage-tube. The quantity of pus that escaped amounted to 45 oz. The relief afforded was again very marked. On the 31st the patient's general condition was not satisfactory. The respirations were 32 and the pulse was 124. The physical signs pointed to effusion in both pleural cavities, which on exploration proved to be purulent. Under chloroform Mr. Byles resected 1 in. of the ninth rib below the angle of the left scapula and allowed 15 oz. of pus to escape; two days later a corresponding portion of rib on the right side was resected with the escape of 20 oz. of pus. Pneumococci were present in the pus from both pleural cavities. On June 4th the patient was comfortable, his pulse had improved, and the temperature was lower (100°). A great quantity of purulent discharge came from all three openings; as that from the pericardium seemed thick and viscid the cavity was washed out daily with a warm solution of boracic acid; no ill effects were observed. The heart sounds could not be distinguished with any accuracy, first on account of pericardial friction and secondly on account of bubbling, metallic sounds varying from time to time and apparently dependent on the amount of fluid present. On the 8th his general condition was not so good; he was thinner and more feeble. His pulse was 120, regular but dicrotic. The respirations were 40 and interrupted by paroxysms of cough which caused him pain over the lower part of the sternum. On June 12th and for the last few days the patient had been more feeble and irritable. After an attack of restlessness he became collapsed and died.

The bacteriological and post-mortem examinations were performed by Professor Kanthack. The pericardial sac was enlarged, but not to any considerable extent; the visceral and parietal layers were thickened and covered with thick pus; there was a little pus in the sac. There were no adhesions. The myocardium was paler than normal and slightly infiltrated just under the pericardium. The interior of the heart presented nothing noteworthy. Both lungs were firmly adherent to the chest wall; a large empyema occupied both sides. The various lobes of the lungs were found firmly adherent to each other; on section they looked greyish in colour and œdematous. They were soft and friable and on gently squeezing them a purulent exudation appeared from the bronchioles. Gangrene and abscesses were not present. The liver presented a typical nutmeg appearance. The kidneys were engorged and cloudy with pale cortex.

The accompanying table represents all the cases of purulent pericarditis treated by operation that I have been able to find in recent literature. In 1883 Dr. S. West[1] read a very complete paper on Purulent Pericarditis before the Royal Medical and Chirurgical Society, giving statistics of paracentesis pericardii; the cases I have collected are since this date, but I do not suppose the list is a complete one. Purulent pericarditis is not a common affection and appears usually as a complication in some infective disease. Of these it is stated that it occurs most frequently in pyæmia; the cases in the accompanying list bear out this point. Among other causes assigned may be mentioned pneumonia and influenza. There are a certain number of cases, however, in which no apparent cause can be found and I would suggest that some of these cases of idiopathic purulent pericarditis may be explained by the spread of inflammation from the mediastinal glands to the pericardium. That this occurs in cases of tubercle is well known.[2] A point of great interest, and one for which no explanation has been offered, is the frequent absence of any pericardial friction sounds; in several of the cases given it was expressly stated in the notes that pericardial friction was not heard. In Ziemssen's Cyclopædia[3] Bauer quotes "the opinion that the friction murmur is often absent in purulent pericarditis," but thinks it is erroneous. Its possible absence is a point to be remembered, for it tends very greatly to increase the difficulty of diagnosis.

It will be noted in several of the cases quoted that effusion into the pleural cavities took place, more frequently into the left than the right. Furthermore the effusion in many cases was serous; this seems to imply that it is not dependent on a direct spread of inflammation to the pleura, otherwise one would expect the effusion to be purulent. The only explanation I have to offer is a physical one—namely, that it is consequent upon pressure on the vessels at the root of the lung. The presence of a left pleural effusion adds very much to the difficulty of diagnosing a pericardial effusion; the converse that a pericardial effusion may simulate a pleural effusion has several times been shown to be correct. In two cases given ribs were resected under the idea that an empyema was being dealt with. A dilated heart has been mistaken frequently for a pericardial effusion. There are no physical signs that I am aware of whereby the nature of the fluid can be diagnosed; in cases of pyæmia it may be surmised, but the presence of pus in the syringe of the exploring needle is usually the first indication of the nature of the effusion.

Paracentesis pericardii has been performed so often and with such signal success that it is quite unnecessary to enter into any discussion as to the justifiability of such an operation. A few words, however, may not be out of place as to the nature and seat of the operation. As regards the site of the incision there is still much difference of opinion and from the list of cases it will be seen that different sites have been chosen; in the majority it is on the left side of the sternum in the fourth or fifth interspace. Dieulafoy injected fluid into the pericardium after death and found that the pericardium as it became distended stretched away in all directions from the base of the heart; also that the heart itself was gradually raised. He recommended the fifth space on the left side about 1 in. from the edge of the sternum, a spot at which there is little chance of wounding the heart or internal mammary artery. Mr. Parker,[4] as the result of his investigations in children, advises the fourth left interspace close to the sternum. A space close to the sternum in the corresponding space on the right side has been recommended by Rotch,[5] but I do not see that it has any advantage over the place indicated by Dieulafoy, and the chance of injuring important structures seems greater. After an exploratory puncture has been made and pus demonstrated it is better to make an incision in the same spot or, if the ribs be too close together, in the space above, for frequent aspiration has been proved to be of no avail. The large quantity of fluid that the pericardium will hold is noteworthy and it is of

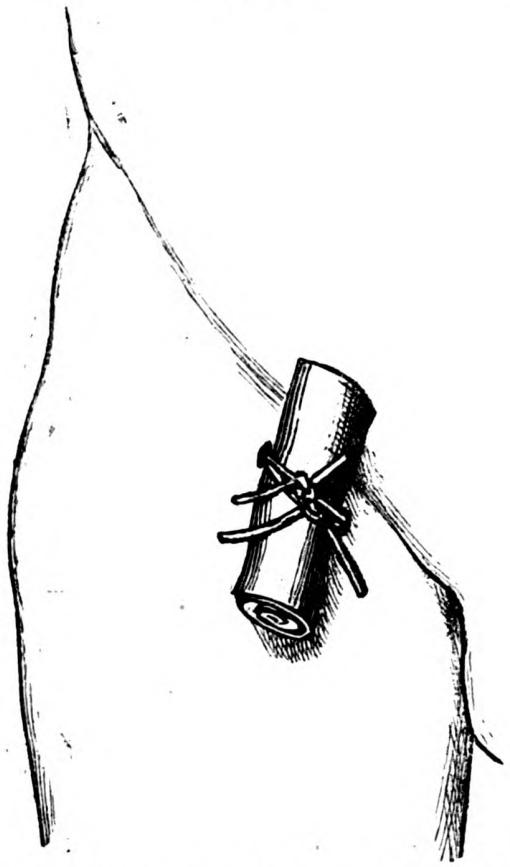
A TABLE OF SEVENTEEN CASES OF PURULENT PERICARDITIS TREATED BY OPERATION.

No.	Reference and name.	Sex.	Age: years	Cause.	Clinical history.	Nature and seat of operation.	Fluid.	Recovery or death.	Necropsy.
1	Medical News, vol. xlvi., 1885, p. 69. Professor Gussenbauer.	M.	13	Pyæmia.	Fall on the shoulder; osteomyelitis.	Five ribs resected on the left side; pericardium washed out.	Pus.	Recovery.	—
2	THE LANCET, March 29th, 1884, p. 560. Dr. Ashby.	?	½	?	Dull over the sternum; fluctuating swelling over the ensiform cartilage.	Incision over the ensiform cartilage.	Pus.	Death.	Pus in pericardium connected by sinus with the incision.
3	London Medical Record, vol. xiii., p. 330. From Russia.	F.	35	Pyæmia.	After a fall intense dyspnœa, cyanosis.	Aspiration in fourth left space; incision in fourth left space close to sternum; pericardium washed out.	Pus, 120 c.c., 2 fluid lb.	Death 18 hours after.	Pericardium thickened; heart, large cavities flabby; right pleural effusion serous.
4	Brit. Med. Jour. vol. i., 1885 p. 1246. Dr. Raven.	M.	30	?	Pain in right side; dyspnœa; no pericardial friction.	Aspiration twice; place not stated.	Pus, 2 quarts.	Death.	Pericardium thickened; old adhesion between apex and pericardium.
5	Australian Medical Journal, 1885, vol. ix., p. 525. Dr. F. J. Newman.	M.	32	With enteric fever.	Enteric, pericardial friction; pleural effusion.	Aspiration four times; incision in third left space; pericardium washed out.	Pus, 36 oz.	Death 54 days after aspiration.	Pericardium thickened; on raising skin a sinus appeared in the 2nd left space leading into pericardial sac. Right empyema; left pleural effusion serous.
6	New York Medical Journal, vol. xlviii, p. 232. Dr. Doubleday.	M.	26	?	Pain in left side; cyanosis, dyspnœa; pleural effusion both sides, serous.	Aspiration 8 times in fifth and sixth spaces.	Pus.	Death 34 days after first aspiration.	Pericardium thickened. Pleural effusions serous.
7	Transactions of the Clinical Society, 1888, vol. xxii., p. 43. Dr. H. Dickinson.	M.	10	Pyæmia.	Cyanosis; no pericardial friction heard. Left pleural effusion serous.	Aspiration in right space close to sternum three times. Incision same place.	Pus.	Recovery.	
8	Transactions of the Clinical Society, 1888. Vol. xxii., p. 60. Mr. Parker.	F.	8	Pyæmia.	Necrosis of tibia.	Aspiration in fourth left space; Incision resection of fifth left costal cartilage.	Pus.	Death.	Much lymph over pericardium.
9	Brit. Med. Jour., vol. i., 1891, p. 360. Dr. Bronner.	F.	11	Influenza.	Influenza; pneumonia; right empyema; no friction heard.	Exploratory puncture followed by incision in fourth left space 1 in. from sternum; pericardium washed out.	Pus, 2 pints.	Death 26 days after operation.	No necropsy.
10	Medical Press and Circular, 1891, p. 244. Dr. P. Davidson.	M.	6½	?	Pain in left side; empyema; no pericardial friction.	Exploratory puncture followed by incision in fourth left space 1 in. from sternum.	Pus.	Recovery; tube removed 35 days after operation.	
11	Transactions of the Association of American Physicians, vol. xii., p. 197. Dr. Shattuck.	M.	26	Pneumonia.	Pericardial friction; left empyema.	Aspiration in fifth left space 1 in. external to nipple; incision same place.	Pus, 1 pint; 2 pints.	Recovery.	
12	Edinburgh Hospital Reports, 1896, vol. iv., p 200. Dr. Underhill.	F.	6	Pyæmia.	Acute necrosis. No pericardial friction. Hæmorrhage after incision.	Aspiration twice, fifth space. Incision same place.	Pus, 4½ oz., 17 oz., 10 oz.	Death 11 days after aspiration.	Pericardium thickened. Source of hæmorrhage not found. Left empyema.
13	Transactions of the Royal Academy of Medicine, Ireland, 1896. vol. xiv., p. 106. Mr. J. O'Connor	M.	11	Pneumonia.	Right lobar pneumonia. No pericardial friction. Left pleural effusion.	Aspiration fourth left space; incision same place.	Pus, 30 oz.	Death 34 days after operation.	Pericardial layers adherent. Left pleural effusion serous.
14	Brit. Med. Jour., vol. ii., 1896, p. 1504. Dr. Robinson.	M.	16	?	Diaphragmatic pleurisy; pericardial friction.	Incision sixth left rib; resected in lateral region.	Pus, 2 quarts.	Recovery; tube removed 61 days after operation.	—
15	Professor Bradbury.	M.	22	Pneumonia.	No pericardial friction; double empyema.	Aspiration fourth space 1 in. from sternum; incision same place.	Pus, 24 oz., 45 oz.	Death 18 days after aspiration.	Thickened pericardium; double empyema.
16	University Medical Magazine, Philadelphia, January, 1893. Dr. Osler.	M.	36	Pyæmia.	Necrosis of nasal bones; no pericardial friction heard.	Aspiration and incision in fourth left space, midway between nipple and sternum.	Serous pus, 2 pints.	Death 18 days after operation.	No necropsy.
17	Abstract in University Medical Magazine, Philadelphia, vol. vii., 1894-5, p. 876. Von Biselberg.	M.	17	?	Punctured wound over cardiac area; this healed and was followed later by pericarditis.	Aspiration 3 times; incision and resection of fourth left costal cartilage.	Pus.	Recovery.	—

interest to observe the effort nature makes provided the patient live long enough to get rid of a purulent effusion. There are two places in which the pus may point. In Case 2 an abscess was opened over the ensiform cartilage, which post mortem was found to be connected by a sinus with the pericardium.

In Case 5 the pus had burrowed forward and would have pointed in the second left interspace close to the sternum. To Professor Rosentein of Leyden is due the credit of being the first to incise and drain the pericardium, the patient recovering completely; the second case, which was also successful, was a patient under the care of Dr. West. Since then the operation has been performed with varying success. Of the 17 cases tabulated 6 are reported to have recovered, but the cases are too few to draw up any reliable statistics. Incision into the pericardium has now been done a sufficient number of times to make it clear that there is no great difficulty or danger about the operation, and I think it must be allowed that it offers the only reasonable hope of recovery to a patient suffering from purulent pericarditis.



Leicester.

A SIMPLE METHOD FOR CONTROLLING HÆMORRHAGE DURING DISARTICULATION AT THE HIP.

BY J. LYNN THOMAS, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CARDIFF INFIRMARY; CONSULTING SURGEON TO THE CARDIFF PROVIDENT DISPENSARY.

IN emergencies the ideal method for controlling hæmorrhage in amputation at the hip-joint is undoubtedly that which requires no special instruments in one's operation bag. Perhaps the majority of the younger surgeons do not

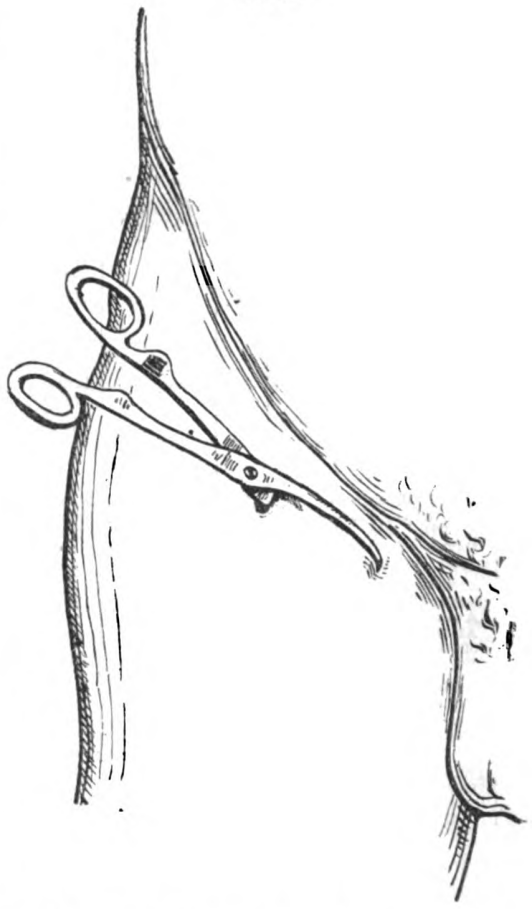


FIG. 1.

realise that the loss of blood is quite insignificant in disarticulation of the hip by the anterior rachet incision because the femoral artery and vein are ligated at the outset of the operation (Treves). I should think the amount of blood lost is less than the quantity of blood driven into the body by vertical elevation of the limb for a couple of minutes prior to the operation. In a properly equipped operation room surrounded by competent assistants the surgeon can adopt either a simple or a complicated method of arresting the hæmorrhage with equal comfort and confidence of success, but in a badly lighted room with incompetent or inefficient assistance in a private house amputation at the hip becomes a very serious and anxious undertaking, unless one happens to possess two one-foot skewers and at least two yards of indiarubber tubing in the operation bag (Wyeth's). In Swain's "Surgical Emergencies" (fifth edition) Davy's lever and Jordan Lloyd's methods are the only two referred to in connexion with the arrest of hæmorrhage in disarticulation of the hip. The first method is practically obsolete, though extremely ingenious, and very few men are *au fait* with the other method.

During the last twelve months I have had to disarticulate at the hip on three occasions, once at the infirmary and twice in private practice, (1) for sarcoma of the femur, (2) for osteomyelitis of the femur, and (3) for an injury. On one occasion I used with satisfaction the following method. The common

FIG. 2.

femoral artery and vein were temporarily compressed immediately below Poupart's ligament. At this point the artery is quite superficial and easily felt and is well above the origin of the deep femoral artery. The femoral pulse being felt I made two stab punctures in the skin, one about an inch outside the pulse and the other about two inches to its inner side—i.e., immediately below the pubic spine. An aneurysm needle with two eyes (Horsley's pattern), which I always carry in my bag, was pushed from one stab-puncture well behind the artery and vein to the other stab-puncture and two long, thick silk ligatures were carried through in withdrawing the needle, then a pad of Gamgee tissue was rolled up and placed over the artery between the punctures and the two silks were tied separately over the Gamgee

tissue, and thus the vessels were efficiently and satisfactorily occluded during the operation. Fig. 1 conveys at a glance the principle involved in this method. It is advisable to simply tie the first stage only of the surgeon's knot and clamp it with forceps and by this means we can easily re-tie if necessary when letting go after ligating the visible blood-vessels on the face of the stump. The only condition which might embarrass one in adopting this method of controlling hæmorrhage in amputation at the hip would be the occurrence of an irreducible femoral hernia. Fig. 2 illustrates a method of controlling the same vessels by means of a large Doyen's broad ligament forceps; there is only one puncture made on the outer side of the femoral pulse and one blade is forced through behind the vessels and then the forceps is clamped. This method would be quicker and would take only a few seconds to apply, but it means the acquisition of a special instrument which is not in every operation-bag, whilst the first method requires nothing beyond the essentials of every operation-bag.

I am not aware that the principle of under-running the vessels with silk and tying it over them has been applied to the common femoral vessels before, whilst it is a recognised method of treating cirsoid aneurysm of the scalp. It is hardly necessary to add that after placing the ligatures and pad (in the method I once adopted successfully) it is necessary to elevate the limb to drain it of its blood before tying the knot tightly. If one were amputating at the shoulder-joint single-handed the same method would be found very useful.

My best thanks are due to my friend Mr. S. W. Allen for the two illustrations.

Cardiff.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ERYTHEMA NODOSUM ET BULLOSUM.

BY J. A. GIBB, M.B., C.M. ABERD.

THE following case in a male patient has recently occurred in my practice. The uncommon character of the affection may make its report of some interest to the readers of THE LANCET. The patient had undergone a considerable amount of climatic exposure prior to the attack, which commenced on March 5th of this year with stiffness in the jaws and pain in the limbs. On the 7th I was called in and I found the patient in the following condition. He was in bed and was sweating profusely. The left knee was enlarged and red but was not painful, and there was no œdema. On the inner side of the right tendo Achillis were several large erythematous spots, oval in shape and of about the size of a half-crown. The same condition existed over the condyles of both humeri extending some little way down the ulnar side of the forearm. Both elbow-joints were enlarged but there was no œdema. The temperature was 99° F. and the pulse was 92. The treatment adopted was the administration of salicylate of soda and bicarbonate of soda, and a free action of the bowels was obtained. I again saw the patient on the 9th. The left knee was quite normal in appearance and the spots on the right leg had all but disappeared. The whole of the left arm was very much swollen, tense, and hard from the shoulder to the finger-tips. The right arm was the same, but in addition on the inner aspect of the humerus was a bullous eruption consisting of six large red blebs each of about the size of a pigeon's egg. One of the bullæ was surrounded at its base by a number of smaller vesicles on a red base. Although there were no bullæ on the left arm the whole of the inner aspect of the humerus had the appearance of a bruise in the first stage, the same as the right arm with the exception of the bullæ. The temperature was 101°. The tongue was red. The patient had been restless all night and complained that he saw a number of steam-engines and various mechanical things which he knew nothing about. I ordered him a sleeping draught of the solution of hydrochlorate of morphia. On the 10th the left arm was considerably improved, the redness disappearing in the ordinary stages of a bruise. The right arm was still very much swollen and there was a good deal of œdema. The temperature was normal. I now gave the patient one-grain doses of quinine and continued it for two days with no marked result. On the 12th I started giving him arsenic in five-minim doses three times a day. This was continued until April 1st, when I discontinued seeing the patient. By that time he had regained normal movement about the elbow-joints. The bullæ had ruptured and were quite healed with no scarring and very little pigmentation. On looking up the subject I find that cases of bullous erythema have been recorded by Dr. Duffin, Dr. Crocker, Dr. Frederick Taylor, and Dr. Pye-Smith. Although the bullous eruption was not symmetrical, yet the discoloration was the same in both arms, and both elbow-joints were affected at the same time and in the same way. Its combination with erythema nodosum inclines me to think that this case was one of erythema bullosum and not pemphigus. There was never any heart affection throughout the case. I examined the patient from time to time. There was no sugar or albumin in the urine. He was always a healthy man. He could only remember being ill once before and that was from typhoid fever. He was fifty-six years old and robust.

Aston-Upthorpe, Berkshire.

TUMOUR OF THE KIDNEY CONTAINING EMBRYONIC MUSCLE FIBRES.

BY BRUCE BUCHANAN MORTON, M.B., C.M. GLASG.

ON account of the rarity of such cases a short clinical description and pathological report of the following case will probably be of interest.

On Nov. 24th, 1897, Dr. Johnstone, Whetley Hill, Bradford, requested me to visit a male child, aged two years, who had a large abdominal swelling, first noticed four months previously and since growing rapidly. No pain or tenderness was complained of by the little one, who took his food well but had of late months lost flesh and suffered from periods of constipation which had to be relieved by medicine. The tumour occupied the whole abdominal cavity; it bulged rather more to the left side and forwards and there were distended veins overlying it. It was smooth, hard, and moveable in a limited range towards the middle line. Percussion was absolutely dull over the whole area of the swelling, with a tympanitic note in the right side flank only. The tumour felt heavy and solid and was probably of the size of a small football. The urine was reported by Dr. Johnstone to be free from blood or albumin. With his concurrence, considering the probability of malignant conditions and the early and high mortality after removal of such tumours, no operation was advised. The child lingered till Christmas Day and seemed to die from starvation by general pressure and flattening causing chronic intestinal obstruction.

At the post-mortem examination, which was confined to the abdomen, the tumour was found to have its base in the left lumbar and hypochondriac regions; it was covered by layers of descending meso-colon, the descending colon itself being stretched and flattened over it from above downwards. The rest of the intestines lay empty, collapsed, and flattened in the right flank. The right kidney was normal in all respects, as was its suprarenal body. This on the left side was not found but may have been atrophied by the pressure of the large tumour which seemed to spring from the sinus of the kidney or the loose tissue surrounding the hilum, the pelvis of the kidney and the ureter being free from growth and only compressed, as also was the kidney proper, which lay opened out as two leaves from its anterior to its posterior border. There were no enlarged glands in the abdomen. Both testes had descended. The tumour itself weighed 6lb. 2 oz.; it had a tense, thick capsule and was spherical in shape. On section an outer white or pink rind was seen 1½ in. in thickness and like the outer fatty layer of a ham. This enclosed an inner mass of softer substance streaked with pink tracts and reddish-brown areas and with scattered hæmorrhages. Further, towards the base of the tumour, a large clot was turned out. A hard nodule was felt at the inner margin of the rind and was removed for examination. The tumour, kidney, and ureter were removed to the museum of Bradford Infirmary. The renal vessels of the left side were in calibre much above normal or those of the

right side. On microscopical examination of the hard nodule referred to it was found to be wholly composed of embryonic muscular fibres; these were as a field of loose bundles and were seen to be striped on moderately careful focussing. There were also large vessels showing endarteritic processes, and here and there the adventitia of vessels seemed to be proliferating. The large mass of the growth (i.e., rind and parts of inner area not destroyed by hæmorrhages) seemed to consist of groups and islets of round cells separated from each other by bands of spindle elements. Within these groups of round cells were numerous vessels and also what appeared to be tubules. The round cells appeared to have in places arisen from the vessels. Fibrous tissue was very scanty in the tumour. For the microscopical interpretation I am indebted to the reports of friends in Bradford, and to the report of the Clinical Research Association, and all I now acknowledge. The tumour was shown at the January meeting of the Bradford Medico-Chirurgical Society, and also at the March meeting of the Pathological Society of Manchester by Dr. Eurich of Bradford, who suggests that the specimen be classed as a teratoma and who describes it as an angio-myosarcoma. The presence of numerous tubules and their relation to the tumour, also the inclusion of embryonic muscular fibres, I cannot pretend to account for. The origin of such tumours from remains of the Wolffian bodies or the statement which has been advanced relative to the close anatomical relationship in the embryo of the muscle plates of the protovertebral somites with the intermediate cell-mass are amongst interesting suggestions on a matter still *sub judice*. The opinions of any of the readers of THE LANCET who may have specially observed such cases would be interesting to the profession.

NOTES OF A CASE OF XEROSTOMIA (MOUTH-DRYNESS).

BY ARTHUR J. SHARP, M.D. LOND., F.R.C.S. ENG.

A SINGLE woman, aged forty-one years, consulted me in February last for constant dryness of the mouth. Her family and personal history were alike good, and except for the local trouble she had never been better in her life. She admitted no history of nervousness or nervous shock. For nearly twenty years, however, she had been troubled with painful sensations at the bottom of the back which were only aggravated by professional treatment but which disappeared suddenly and effectually after taking a single bottle of tonic medicine bought at a druggist's. Her dentist (Mr. E. Burrows, who kindly sent her to me) had found her mouth unduly sensitive and had blamed her "nerves" as being the cause of her symptoms. She had never had neuralgia. She had had influenza seven or eight years ago, and had had very occasional headaches, but not lately. The dryness dated from October, 1896, when it came on rather suddenly. She taught at a Sunday school and had found it impossible to do so without constantly sipping water. The tongue was worst during the first winter. During the last winter she had had several colds in the head and the dryness had always been worse on these occasions. Hot or spicy food or fluids she had neither cared for nor been able to take. The dryness was worst out of doors or by a fireside. The secretion of tears was not affected; the eyes looked irritable and developed a little gummy discharge at night. She had always been "shortsighted," and strong winds made the eyes water and so did reading at night. She said that she could smell and taste perfectly and had no complaint to make about the nose. A brief examination gave the impression that the mucous membrane was pale and somewhat dry. No obstruction could be found nor any dry crusts, but a musty smell often associated with such conditions was recognisable. When she had a cold she used as many handkerchiefs as anyone else. The teeth were not specially bad; several had been stopped at various times and she had lost some of the back ones. Lately she had worn some artificial ones; the dryness was aggravated if they were disused. She had no difficulty in chewing or swallowing with the aid of frequent sips of fluid. The mucous membrane lining the lips, gums, cheeks, tongue, and palate was dry and glazed. The fauces and pharyngeal wall were granular, but the dryness only extended to the base of the tongue. One or two strings of dry mucus were seen in the mouth and there was always a quantity adherent to the teeth and lips in the morning. The tip of the tongue was red; the rest of it was pale. The surface was granular with papillæ, some fungiform ones near the tip being especially prominent. There were no inflamed patches and only a few very shallow transverse furrows. The papillæ of the salivary ducts were not prominent and no secretion could be expressed from them. After moistening the tongue with water a very faintly alkaline reaction was obtained to litmus paper. The lips were dry and peeling. There were a few pustules about the forehead, the face and lips, and the hands and forearms. These were attributed to scratches received in gardening. The angle of the mouth on the left side was scarred. The skin was not unduly dry and the patient perspired freely on the least exertion. Last summer she had some swelling of the eye-lids which cleared up after a short time, otherwise she was very well at that time. I regret that I was unable to obtain a specimen of the patient's urine. She was not anæmic and there appeared to be no urinary disorder. She was not subject to parotitis and there were no signs of pressure on any part of the salivary apparatus. She had cooled her tongue with a solution of sodium carbonate followed by cold water. She has taken mercuric iodide in medium doses with quassia and describes herself as improving.

The condition appears to be a general absence of moisture from the mouth, with perhaps a slighter similar affection of the nose. One feels inclined either to attribute it to causes resident within the nervous system or else to regard it as allied to those granular atrophic phases of deficient secretion met with in the nose, fauces, pharynx, and conjunctiva. I am much indebted to Dr. Hall of Sheffield for kindly referring me to Professor Fraser's paper in the *Edinburgh Hospital Reports* for 1893, which contains a table of the nineteen cases recorded up to that time.

Whitby, Yorks.

YERBA SANTA IN INFLUENZA.

BY JOSEPH WESTMORLAND, L.R.C.P. EDIN., M.R.C.S. ENG.

DURING the year 1896 my son and I, at that time residing in California, decided to go on a hunting and fishing excursion up into the Sierra Madre range of mountains, a guide—an Englishman, who provided us with mules and burros to convey ourselves and baggage to our destination—accompanying us. On our way up the trail the guide pointed out to us many plants and shrubs, amongst others yerba santa (herb of the saints, as he named it), saying that it was the best thing he knew for any catarrhal affection, especially for a cough, and speaking highly of its beneficial effects on himself. He also told us that the Mexicans, or "greasers," as they are generally named, used it constantly for the above-mentioned purpose and considered that there was nothing equal to it. Shortly after my return home to Los Angeles from this expedition I was summoned to attend two young Englishmen who were suffering from smart attacks of influenza. After the febrile stage had subsided both of them were affected with the very troublesome cough which so often supervenes at this stage of the attack. Bearing in mind what I had heard about yerba santa when up in the mountains I decided to give it a trial; so I prescribed it for these patients, with the result that in both cases the cough was speedily relieved and soon cured.

Whilst out in California I prescribed it in a few other cases for the cough supervening on influenza with equally good results. This has led me to draw the attention of readers of THE LANCET to this little used plant. In the fourth edition of Martindale and Westcott's Extra Pharmacopœia, p. 341, the following passage occurs: "Yerba Santa (*Eriodictyon glutinosum* or *E. Californicum*).—Leaves are aromatic and sweetish, often agglutinated together; they are stimulant to mucous membranes of the bronchial tubes. Used for bronchitis, phthisis, and other catarrhal affections. Fluid extract, 10 to 40 minims. Is sold combined with extract of malt, as Malto-Yerbine. Dose, 1 to 4 drachms." It will thus be seen that it has also been used for bronchitis and phthisis. I directed my patients to take an ounce of the leaves of yerba santa, pour upon them one and a half pints of boiling water, then mix in about three ounces of honey and boil down to about three-quarters of a pint. Of this linctus

they took two or three teaspoonfuls every few hours or when the cough was at all troublesome.

Macclesfield.

ANEURYSM OF THE ABDOMINAL AORTA IN A CHILD.

BY ROBERT Y. AITKEN, M.D. GLASG.

ANEURYSM under the age of twenty years is rare, although instances have been recorded by Dr. A. Jacobi, and one occurring in a child, aged nine years, has been reported by Syme.

In the following case, which was under the care of Dr. J. S. Watson, the patient was a boy, aged nine years, who was admitted to the Blackburn and East Lancashire Infirmary on Jan. 10th, 1898. He was suffering from heart disease, both aortic and mitral valves being affected. He died on Feb 5th and at the post-mortem examination an aneurysm of the size of a golf-ball was found projecting from the anterior wall of the abdominal aorta at its bifurcation into the common iliac arteries. The aneurysm was full of soft blood-clot and the opening into the right common iliac artery was found to be blocked by an embolus. The aortic valves were much diseased, one of the flaps being perforated. At two points in the ascending aorta there were spots of atheroma which bulged slightly outwards and no doubt represented the commencement of other aneurysms. The usual causes of aneurysm in children are injury and embolus. Here the cause was obviously the latter. During life the aneurysm was not suspected. The child's only complaint was of pain in the chest and no change in colour or temperature was noticed in the leg.

ST. MARY'S HOSPITAL.

A CASE OF SIMULTANEOUS LIGATION OF THE POPLITEAL ARTERY AND VEIN; RECOVERY WITHOUT GANGRENE.

(Under the care of Mr. EDMUND OWEN.)

WE are able to publish this week two cases of an operation which is decidedly rare—namely, simultaneous ligature of the popliteal artery and vein, and in each case the operation was performed for injury of these vessels, though in one the ligatures were applied immediately after the accident, while in the other the vessels were not tied until a month later when an arterio-venous aneurysm had fully formed. The general opinion of surgeons up to a very recent date has been so decidedly adverse to simultaneous ligature of both the popliteal artery and vein that it has even been suggested that it would be well to amputate at once at the knee should both these vessels be wounded, and amputation at the hip has been proposed for wound of the femoral artery and vein. These views are in great part based on the results obtained in pre-antiseptic days. Gangrene was much more prone to follow simultaneous ligature of both the large vessels of a limb at a time when suppuration was almost certain to occur in the wound, as by inducing œdema it would add a further difficulty to the circulation in the part. The cases recorded show that on the whole gangrene is less likely to follow if the vessels are not tied at once but after an interval, so that the collateral circulation has had some time to be established. In most of the cases in which the popliteal artery and vein have been tied an aneurysmal varix or varicose aneurysm had already formed. Mr. Newbolt, as will be seen by the report which follows, has collected seven cases, and we may mention eight other similar cases. They are described by B. F. Curtis,[1] Scriba,[2] Félizet,[3] Trélat,[4] Reynier,[5] Reinhold,[6] and Chaput.[7] In all these cases a favourable result followed, no gangrene occurring. Even in Mr. Newbolt's list gangrene only followed in a case which occurred so long ago as 1851. It may fairly be concluded from a study of these 15 cases that the popliteal artery and vein may be simultaneously tied after injury, either at once or when an arterio-venous aneurysm has formed, with very much less risk of gangrene than has hitherto been considered probable. For the notes of this case we are indebted to Mr. E. W. Holycak, the dresser.

A married woman, aged thirty-five years, was admitted to St. Mary's Hospital in November, 1897, with necrosis of the lower end of the left femur. There was no history of syphilis or tubercle, but there was of injury, for at the age of fourteen years, when she was climbing over a gate, she got her leg caught between the two top bars and falling forward severely hurt her thigh. "Shortly afterwards she was operated on in the Reading Hospital and twelve months later several pieces of bone came away through sinuses persisting after the operation. Five years later a sinus formed on the outer and lower part of the thigh." When she entered St. Mary's Hospital there were three sinuses discharging and she said that they had been in that condition for "many years." The femur was greatly thickened. Mr. Owen cut down upon the bone between the ilio-tibial band and the tendon of the biceps and removed a sequestrum 4 in. long, and about two months later the woman left the hospital apparently convalescent. But as the sinuses continued to discharge she was readmitted, and on March 7th of this year Mr. Owen made a further examination, laying open the wound which he had previously made. On passing his finger inwards in front of the popliteal vessels he detected an opening in the shaft of the femur, but as it was impossible to deal with it from the outer side he made an incision down the front of the tendon of the semi-membranosus. The tissues about the femur were firmly matted together, and in endeavouring to raise them from the back of the femur the superior internal articular artery was torn out of its origin in such a manner that there was no alternative but to dissect out the popliteal artery from its bed and to tie it in two places, cutting it across at the wounded spot. When this was done it was found that the popliteal vein had been similarly damaged. It was therefore tied in two places and cut across. The operation on the bone having then been completed the wound was gently packed with gauze, the limb wrapped in cotton wool and comfortably and securely fixed on pillows, the foot of the bed being slightly raised. "The limb has been markedly anæmic and somewhat shiny, but sensation has never been lost. No pulsation could be felt in the anterior and posterior tibial arteries on April 16th. The cavity is granulating up and she is putting on flesh."

Remarks by Mr. OWEN.—On the conclusion of the operation, in the course of some clinical remarks I explained the seriousness of the disaster which had befallen the patient, and I deemed it fair to attribute it to the matted and unyielding condition of the tissues overlying the diseased bone, the result of an inflammation which had been lurking in that neighbourhood for over twenty years. I said that I feared gangrene of the limb was almost inevitable, but that it was just possible that under the influence of the long-continued inflammation there might be such a considerable development of new blood-vessels that collateral circulation had a slightly better chance of becoming established than if there had been no such antecedent. I need hardly say that as I visited the case day by day and noted the absence of signs of gangrene the relief which I experienced was considerable. Cases of recovery without gangrene of the limb after simultaneous ligation of the popliteal artery and vein are of sufficient rarity to render a record of them desirable, and it would be interesting to know to what extent the probability of so favourable an issue is likely to be modified by the circumstances in which the ligation is resorted to. I cannot conclude this report without the expression of thanks to my house surgeon, Mr. A. Brodribb, for the able help which he gave me in the case.

STANLEY HOSPITAL, LIVERPOOL.

A CASE OF ARTERIO-VENOUS ANEURYSM OF POPLITEAL VESSELS; LIGATURE OF POPLITEAL ARTERY AND VEIN FOUR AND A HALF WEEKS AFTER THE INJURY; RECOVERY.

(Under the care of Mr. G. P. NEWBOLT.)

CASES of arterio-venous aneurysm are always of interest and since the old custom of bleeding from the veins of the arm over the site of the brachial artery has practically become obsolete they are few and far between.

A man, aged twenty-three years, was admitted into the Stanley Hospital, Liverpool, on Jan. 27th, 1898, suffering from a pulsating tumour situated in the upper and outer portion of the calf of the right leg. The patient said that four weeks previously he struck his right leg against a long spicule of plate-glass and this inflicted a wound on the outer side of his leg. When the glass was pulled out very profuse hæmorrhage occurred; the blood was bright red in colour and he thought that he lost about "two quarts." The wound was attended to, the limb was bound up, and he went home in a cab. A day or two after the infliction of the injury he had cramp-like pains in the leg; these persisted, but the wound healed and he was able to get about, in fact, when Mr. Newbolt saw the patient he walked easily and well. He consulted Mr. Newbolt for the first time on Jan. 24th. There was then a recently healed cicatrix on the outer side of the right leg half an inch below the head of the fibula. A firm pulsating mass of the size of an orange occupied the upper and outer portion of the calf and extended upwards into the lower portion of the popliteal space. When he was admitted into hospital three days later the swelling was larger, the circumference of the leg being 14½ in. as compared with 12 in. on the opposite side. The tumour had distensile pulsation and there was a loud bruit, but no enlargement of the veins below and no œdema of the foot were noted. The posterior tibial artery pulsated but feebly in comparison with that of the opposite side. On raising the limb the swelling became somewhat smaller and on controlling the femoral artery the pulsation disappeared and the size of the tumour diminished. At this time Mr. Newbolt had no suspicion that the vein was implicated and thought that he had to deal with an aneurysm of the posterior tibial or popliteal. On Jan. 28th the patient was put under chloroform. On removal of the dressings it was evident that the size of the aneurysm had increased and there was very distinct pulsation at the lower part of the popliteal space on the inner side; the tumour here felt softer and was evidently spreading in this direction. The patient having been turned on his face and a tourniquet having been placed round the upper part of the thigh a free incision was made over the most prominent portion of the tumour and the outer head of the gastrocnemius was cut through except at its upper and outer side. The sac, which was very thin, was opened and about two handfuls of clot were turned out; sponges were then plugged into the wound. On removing them the artery was seen lying to the inner and posterior side of the sac and in its wall was a hole with rounded edges of the size of a large pea from which dark venous blood oozed. A probe was passed upwards and downwards and also for some depth inwards. The sac wall was very thin and was composed of the surrounding compressed tissues covered with a lining of fibrin. The main contents consisted of clotted blood, but there was also a good deal of fluid blood in the sac and this structure itself was pouched in several places. Mr. Newbolt now separated the artery from the vein, which lay collapsed to the inner side and overlapped the artery. Opposite the wound in the artery, however, the vein was adherent and could not be separated and a probe passed from the artery into the vein. In order to tie the artery above the wound in it Mr. Newbolt had to extend his incision upwards, exposing the peroneal nerve; the internal popliteal nerve, however, was not seen, being evidently pushed inwards. The artery was next divided and tied above and below with green gut ligature and the longitudinal slit in the vein was closed with a continuous catgut suture. This it may be said was difficult as the wound was a deep one and the light was failing. On loosening the tourniquet there was smart hæmorrhage from the vein and also from a large branch, probably the inferior sural. The vein was therefore ligatured and divided and all other bleeding points were secured. The wound being dry was now thoroughly cleansed from all clot and was lightly packed with cyanide gauze. The whole limb was enveloped in layers of wool and lightly bandaged. The patient was sent back to bed, the leg was raised and warm blankets and hot-water bottles were placed around it. Two hours later the foot was rather cold and no pulsation was to be felt in any of the vessels at the ankle. The operation took one and a half hours and Mr. Newbolt was ably assisted by his colleague Mr. Larkin. On Jan. 29th the patient was quite comfortable. The foot was warm, he could move the toes, and sensation was good. The wound was dressed. On the 31st the wound was dressed; it looked well and was freely open. After this date there was practically nothing to note. The patient made an uninterrupted recovery, the wound rapidly granulated and the temperature was never above 99° F. When Mr. Newbolt examined him on March 17th he was walking about with an elastic stocking on; there was very little tendency of the foot to swell on removing the stocking and the circulation was fairly good, though Mr. Newbolt could not detect pulsation in any of the vessels of the foot.

Remarks by Mr. NEWBOLT.—I have obtained notes of 6 cases in which this operation has been performed for wound of the popliteal vessels; 4 of these occurred in Great Britain, 1 in Germany, and 1 in France. In the 7 cases which I have tabulated several points are interesting. In the first place all the patients except the first made good recoveries and he lost his leg only. In 2 of the 7 immediate ligature was resorted to with good result. In Mr. Langton's case 9 days elapsed and in my own four and a half weeks passed before ligature was applied. Mr. Walsham, in a valuable paper[1] based on a case of ligature of the femoral artery and vein for wound of these vessels, makes the following remarks: "Ligature of the femoral artery and vein immediately after wound is much more serious than when an interval of a few weeks has passed. In 12 cases recorded of immediate ligature (that is, within twenty-four hours) 5 suffered from gangrene and died. In 20 cases after pressure had been applied for some time and the collateral circulation established only 5 suffered from gangrene, though 11 died altogether from various causes—such as secondary hæmorrhage, pyæmia, &c.; 4 cases of removal of tumour complicated by wound of artery and vein were not attended by gangrene, as the collateral circulation had already been established; 16 cases of wound of the femoral artery and vein treated by pressure alone all ended in arterio-venous aneurysm." He therefore draws the conclusion that when a large artery and vein such as the femoral are wounded the safer plan is to apply pressure for a few days until the collateral circulation is established and then to ligature the proximal and distal ends. Immediate ligature of both artery and vein is liable to be attended with gangrene although this risk is less than has been generally assumed. Again, Grillo in 15 cases of aneurysm tied both artery and vein without bad result. Hunter, in his first 3 operations, tied both artery and vein. This, therefore, also emphasises the fact that gangrene is not so common even after ligature of the main artery and vein in the lower extremity as is generally supposed. Mr. Jacobson in the last edition of his "Operative Surgery" says in speaking of wound of the popliteal artery: "It would be well if possible to get leave for immediate amputation if the vein was found injured also." In the case recorded by Mr. Annandale there was an absence of the peculiar thrill which has always been considered diagnostic of arterio-venous aneurysm. There was no dilatation of the canal of the vein and Mr. Annandale does not think that although a wound existed there was much communication through the wound between the vessels. My case rather confirms Mr. Annandale's as there was nothing typical of arterio-venous aneurysm until operation disclosed the state of affairs and the vessels were unaltered in calibre.

If I may draw conclusions from seven cases all occurring in young adults I should say that the operation is not so serious as one would naturally think and that the prognosis will depend greatly upon the amount of blood extravasated in the tissues around. It will of course always be wise to point out to the patient that amputation may be necessary. Finally, after recovery the veins of the leg are prone to become varicose and this is the case in one instance in which the femoral vessels were tied some fourteen years ago, the

limb otherwise being perfect. Ligature of the artery did not stop bleeding from the vein either in my case or in Mr. Walsham's femoral case, though Halford's experiments on rabbits teach us that this is so, and Langenbeck also makes the statement that ligature of the artery often stops hæmorrhage from the vein. The continuous suture of the vein failed, I think, because the glass probably penetrated the posterior wall also and thus inflicted two wounds in the vein only one of which was closed. The slit was too long to be picked up and tied with a ligature.

With regard to treatment, immediate ligature was successful in the 2 cases in which it was carried out and also in the third case, in which it was done nine days after the accident. In the other four, in which pressure and expectant treatment were carried out, there was hæmorrhage in one and in all the others arterio-venous aneurysm formed, needing operation; in one of these the leg was lost. In my own case there was a large collection of blood extravasated and this must have impeded the collateral circulation to a certain degree, though leaving the wound open and clearing out the clot of course relieved matters. There must often be considerable doubt as to whether both vessels have been wounded; but I think, taking all things into consideration, that given a wound of both vessels I should at once cut down and tie the artery and, if possible, sew up the vein. Failing this I should ligature the vein also. An account of the case was read before the Liverpool Medical Institution.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Tuberculous Stricture of the Intestine.—Columnar-celled Carcinoma of the Œsophagus.—Duct Papilloma followed by Colloid Carcinoma.—Contraction of the Stomach.—Aneurysm of the Aorta Rupturing Externally.—Interlobular Cirrhosis of the Liver.—Œsophageal Cancer Ulcerating into the Aorta.—Cerebral Hæmorrhage.—Exhibition of Specimens.

A MEETING of this society was held on April 19th, the PRESIDENT, Dr. J. F. Payne, being in the chair.

Dr. CHARLES POWELL WHITE (Birmingham) showed a specimen of Stricture of the Intestine due to Intestinal Ulceration. The intestines were those of a man, aged fifty-two years, who died from intestinal obstruction. There were numerous ulcers throughout the whole length of the intestines; they were irregular in shape and showed a great tendency to extend around the bowel. The bases of the ulcers were somewhat thickened and in a few of them minute tubercles could be seen. There were four dense cicatricial strictures in the small intestine. Just above the tightest of these, which would not admit a cedar pencil, was a collection of small ulcers, one of which had perforated and given rise to septic peritonitis. The cæcum was extensively ulcerated and just above was a cicatricial stricture of the colon. There were no old adhesions between the intestines and neighbouring parts and there was no sign of tuberculosis elsewhere.—Mr. D'ARCY POWER asked whether the tuberculosis was believed to be primary. He mentioned that Louis XIII. of France died from acute peritonitis due to a similar affection of the intestine.

Dr. WHITE also showed a specimen of Columnar-celled Carcinoma of the Œsophagus. The patient was a man aged forty-seven years. The specimen showed a mass of new growth springing from the anterior wall of the œsophagus just above the cardiac orifice. The mass measured 2 in. long, 1½ in. wide, and 1 in. in depth, and it occupied the lumen of the tube. There were one or two enlarged glands in the neighbourhood of the cardiac orifice. Microscopically it was a typical columnar-celled carcinoma.

Dr. C. E. M. KELLY and Dr. D'ESTE EMERY gave the notes of a case in which a Duct Papilloma of the Breast was followed by Colloid Carcinoma which finally disseminated and caused the patient's death. In 1890 the patient, who was then thirty-nine years of age, had the breast removed for a tumour which proved to be duct papilloma. In 1894 two more tumours appeared and on removal in 1896 they were found to be colloid carcinoma, and the recurrence of colloid carcinoma took place and in 1898 she died with secondary growths in various parts of the body. There were disseminated knots

of colloid cancer in both lungs and a large growth of colloid cancer in the sternum; in the liver, however, where many secondary deposits were found, there was no trace of colloid, the cancer being apparently of the ordinary spheroidal-celled type. The most extraordinary change was in the skull, in which half the frontal bone was replaced by a dense membrane about ¼ in. thick, which was composed of fibrous tissue with alveoli of spheroidal cells, the bone having disappeared except at the edges of the depression, where it was infiltrated with new growth. There was no trace of colloid change in the skull.—Mr. RAYMOND JOHNSON said that he remembered the removal of the breast by Mr. Berkeley Hill. The tumour was a small one midway between the nipple and the edge of the gland and on squeezing it there was a blood-stained discharge from the nipple. It was in a cyst and was of a delicate feathery structure and microscopically had the characters of a simple papilloma. The subsequent growths had nothing in common with this original growth and he thought that they were not recurrences of it. It was more probable that the small tumours near the scar were new developments of cancer in some outlying lobule of the gland which had escaped removal at the time of the operation.—Mr. BETHAM ROBINSON was inclined to take the same view. He referred to a case which he published some years ago in which the growths in the axilla appeared to be quite different to the original one in the breast. This was owing to the glandular recurrences having undergone myxomatous degeneration so that it required careful searching to find an alveolar structure. He thought care should be taken in giving a prognosis not to place too much reliance on a favourable microscopic examination.—Dr. EMERY, in reply, said that there was nothing in the sections of the secondary growths which resembled duct papilloma and he thought that the subsequent growths were independent.

Dr. BERTRAM HUNT showed a case of Extreme Contraction of the Stomach. The specimen was taken from the body of a man, aged fifty-seven years, who died with gastric symptoms, the illness lasting seven months. The stomach was converted into a tubular organ, the walls being greatly thickened, especially at the centre and pyloric end. The cavity was so reduced that it could not contain more than 1½ oz. of fluid and the lumen in the centre would only just allow the passage of a No. 11 English catheter. Microscopical examination showed that the thickening was chiefly in the submucous and muscular coats and was due to diffuse infiltration by glandular carcinoma, which had undergone extensive colloid degeneration. Many considerations tend to show that the majority of these cases of contracted stomach are due to malignant disease and that many of the cases described as simple cirrhosis or fibrosis ventriculi were really due to cancerous infiltration. The following facts especially support this view: (1) the occurrence of the condition in elderly patients and the short duration of the symptoms, the average duration of ten collected cases being ten months; and (2) the fact that in these cases of contracted stomach growths are often found in other organs not prone to primary malignant disease, such as the mesenteric glands, liver and peritoneum, this association being found in eleven collected cases.

Dr. LEE DICKINSON showed an Aneurysm of the Aorta which ruptured externally. The specimen was obtained from a man, aged thirty-nine years, who had lived temperately and quietly and was free from atheroma and had not had syphilis. It was a very large aneurysm, coming from the first part of the arch of the aorta, which made its way through the sternum and ribs, forming a secondary sac in front of the chest. It proved fatal by external hæmorrhage. The chief interest of the specimen lay in the unusual delicacy of the coats and narrowness of the calibre of the aorta throughout, a condition which Virchow described as hypoplasia and connected particularly with chlorosis and hæmophilia. It was probable that hypoplasia of the aorta deserved recognition as an occasional cause of aneurysm.

Dr. F. PARKES WEBER exhibited a Liver showing an early Interlobular type of Cirrhosis from a case of suppurative pylephlebitis. The fibrosis of the liver could not be made out macroscopically, but microscopically there was a considerable increase in the fibrous substance surrounding the small branches of the portal vein. The distribution of the cirrhotic process was typically the unilobular form described by Charcot and Gombault in their original papers of 1876; the bile capillaries were apparently increased in number. Suppuration in connexion with the pylephlebitis had caused pressure at the hilum of the liver. This had caused intense icterus during at least the latter part of the illness and may possibly have induced the cirrhosis. If the latter hypothesis be the correct one the liver affords a typical example of commencing unilobular cirrhosis caused by obstruction to the flow of bile. In animals two or three days' obstruction to the bile flow (by ligature of the duct) may be sufficient to cause microscopical changes in the liver of a type analogous to those found in the present case—namely, apparent increase in the number of bile capillaries and increase in the amount of interlobular connective tissue. On the other hand, the question arises whether the increase of connective tissue in the present liver be not of earlier origin than the pylephlebitis. So sharply defined are the fibrous interlobular areas that one is reminded of the appearances seen in certain cases of so-called "cystic disease of the liver," such as the case recently shown by Dr. G. F. Still. It is, however, not likely that the fibrosis in the present case is of congenital origin, as it appears to be in cystic disease.

Dr. A. E. GARROD showed a specimen of Perforation of the Aorta by a Malignant Ulcer of the Œsophagus. The patient was a man, aged sixty-two years, who died almost suddenly from hæmorrhage into the stomach. At the necropsy an epitheliomatous ulcer 3 in. across was found affecting the œsophagus about 5 in. from the crico-arytenoid fold and about on a level with the bifurcation of the trachea. It affected chiefly the anterior wall; there was no stenosis. From the floor of the stomach there was a fistulous channel communicating with the descending part of the aorta by a small orifice. There was very little infiltration of the surrounding structures. The stomach contained two pints of blood, but only a little had passed into the duodenum, showing that the hæmorrhage must only have begun a short time before death.—Dr. A. F. VOELCKER said that there was a specimen in the Middlesex Hospital Museum which was almost exactly similar. It was taken from a man, aged fifty-five years, who died from sudden hæmorrhage. Dr. Voelcker remarked on the immunity from infiltration which was usually enjoyed by the arteries although they might be surrounded by growth as in the cases of recurrence in the glands of the neck. The large arteries were seldom invaded, although the veins were often thrombosed.

Dr. L. FREYBERGER showed a Brain with three consecutive hæmorrhages and a Heart (from the same case) showing a well-developed Musculus Papillaris on the Mitral Valve. The patient, a woman, aged forty-three years, was admitted to the Great Northern Central Hospital on Feb. 14th, 1898, under the care of Dr. Clifford Beale. On Dec. 20th, 1897, she complained of violent headache, which came on quite suddenly; soon afterwards she fainted and remained unconscious for two hours, during which time the muscles of the right side of the face and both arms were twitching violently. When she came to there was no paralysis noticed. She was quite well again after six days' illness. Seven weeks after the first attack (on Feb. 7th, 1898) she again complained of severe headache and for a few hours had violent convulsions of the muscles of the right side of her face and body, in the course of which she bit her tongue through, but she was not unconscious. Again there was no paralysis; but after this last attack the patient remained delirious and kept screaming and shouting all this time. Both parents and a brother died from kidney disease. In the hospital she talked and rambled continually but returned sensible answers to questions. On examination she was found to be amblyopic; the pulse was regular and heaving, there were hypertrophy of the heart and a loud systolic murmur at the apex and a ringing second sound in the aorta. No motor paralysis could be made out. On March 17th—i.e., thirty-one days after admission—she fell out of bed while eating her dinner; she was found conscious, lying on the floor, but could not get up. Half an hour afterwards she became suddenly deathly pale and unconscious; the left side of her face and the left arm and leg became completely paralysed and she died a few hours afterwards. At the post-mortem examination three hæmorrhages were found in the brain, one of the size of a cob-nut in the right temporal lobe; the clot was amber-coloured, the brain tissue around was straw-coloured, firm, and dry; a second clot, of the size of a Tangerine orange, and of a greyish-brown colour and gelatinous consistency, was

situated in the left occipito-temporal lobe near the calcar avis; a third large clot (weight 3½ oz.), soft, and of a dark purple colour, was found in the external capsule; the caudate and lenticular nucleus and the optic thalamus were partly destroyed and partly flattened out by the pressure of this huge mass of blood-clot. There was much atheromatosis of the basal arteries. The kidneys were both small and granular. The heart, which was largely hypertrophied, presented an interesting anomaly: from the top of the left lateral papillary muscle a cone-shaped muscle was seen stretching across the ventricular cavity on to the aortic cusp of the mitral valve; it measured ⅝ in. in length and ¼ in. at its base and occupied the place of a tendinous chord. This continuation as it were of the papillary muscle right on to the mitral valve is somewhat rare; it represents a condition present during early fœtal life when a sponge-work of muscular trabeculæ fills the space between the ventricular wall and the primary atrio-ventricular valve.

The following card specimens were exhibited:—

Dr. C. D. GREEN: (1) Stomach with two Perforating Ulcers and a Fistulous Communication with the Colon; and (2) Fibroma of the Nipple.

ÆSCULAPIAN SOCIETY OF LONDON.

Rupture of Tubal Fœtation at the Eighth Week; Laparotomy; Death.—Laparotomy as Treatment in Tuberculous Peritonitis.—Fatal Acute Cardiac Dilatation due to Alcohol.

A MEETING of this society was held on April 15th, Dr. B. G. MORISON, the President, being in the chair.

Dr. J. R. T. CONNER read notes of a case of severe Abdominal Pain in a woman occurring three times between the sixth and eighth week of pregnancy and at the third accession she was blanched and collapsed. Later in the day of the third attack she was operated upon, when the fœtus in its membranes, the placenta entire, and blood-clot from the pelvis of about 1200 c.c. were removed. No drain was used. She rallied from the operation, but the temperature began to rise, reaching 38·3° C. on the fourth night, when delirium was present. The pulse kept always above 100 per minute, and the mental state was that of mania. On the fifth day after operation a decidua was passed per vaginam. Fever continued, reaching on the fifteenth day 40·5° C., and the patient died on the twenty-fifth day.—Mr. A. Q. SILCOCK regarded the result as due to septicæmia.

Mr. A. Q. SILCOCK read a paper on the Treatment of Tuberculous Peritonitis by Laparotomy, in the course of which he quoted statistics from continental authorities and concluded by expressing his belief in favour of abdominal incision. The indications for operation he held to be were when the peritoneum was predominantly affected, when pus or other fluid was free in the abdomen, when a tuberculous focus could be removed; the contra-indications he considered to be general tuberculosis, intestinal ulceration, unless the ulcer has perforated, and advanced pulmonary tuberculosis. He advocated incising in the mesial line below the umbilicus, washing out the abdomen with sterilised water, the avoidance of antiseptics to flush the abdominal cavity, and the use of iodoform gauze as a drain changed every twenty-four hours. He related a case of a child, aged six years, in whom he had so operated for general miliary tuberculous peritonitis, who recovered rapidly and now, eight years later, was well.

Mr. W. CAMPBELL M'DONNELL related a case of Acute Cardiac Dilatation due to alcohol in a man, aged thirty years, without valvular lesion, the liver being unaffected as shown by post-mortem examination.

BRITISH GYNÆCOLOGICAL SOCIETY.

Enucleation of Uterine Myomata.—Exhibition of Specimens.

A MEETING of this society was held on April 14th, Dr. MACNAUGHTON-JONES, President, being in the chair.

Mr. BLAND SUTTON opened a discussion on the subject of the Enucleation of Uterine Myomata arising out of a paper read by Dr. W. Alexander at a previous meeting of the society. He said that continental operators had found that enucleation was attended with more disastrous results than hysterectomy and had one by one given it up. He had himself adopted enucleation in 8 cases; they were all successful and the operation itself was as easy as the enucleation of a cyst from the broad ligament; but there were four important objections to it: (1) the difficulty of hæmorrhage caused by oozing; (2) the protracted convalescence; (3) the length of the operation; and (4) the troublesome sinus. On the other hand, hysterectomy could be done in half an hour; in eighteen days the patient was able to walk about; there was no anxiety about hæmorrhage and there was no sinus. If the two latter factors could be made as satisfactory in the case of enucleation this would be a good operation. Another objection to enucleation was that in most cases fibroids developed after the child-bearing period and the uterus was then a non-vital and unimportant organ. Personally he much preferred hysterectomy, leaving one or both ovaries. The latter was an important point, for he felt sure that a patient was much better off with two ovaries and no uterus than with a uterus and no ovaries.

Dr. W. SMYLY (Dublin) agreed with Mr. Bland Sutton that enucleation was good in a limited number of cases, but that where the woman was past the child-bearing period and the uterus was a useless organ hysterectomy was better. Enucleation was specially indicated in the case of a young woman with one or few myomata. He had operated in five cases; one died from sepsis and the other four recovered and had remained well. Another objection to enucleation was the risk of other fibroids developing later; but perhaps the strongest argument against it was the fact that Martin of Berlin, its originator and main developer, had abandoned it of late.

Dr. GRANVILLE BANTOCK remarked that the novelty in Dr. Alexander's suggestions was not the enucleation itself, but its application to multiple fibroids. He would ask how a case would be dealt with in which there was one fibroid in the anterior and one in the posterior wall. The removal of a dozen or more nodules was a work of supererogation, for such a uterus could be of no use to the patient. He was convinced that there was a tendency to operate too much on fibroids; in many cases they gave rise to no symptoms and the patients were able to bear children, whilst very few cases destroyed life. In view of these facts he thought they ought to stay their hand. The more experience he had the less he was inclined to operate.

Mr. BOWREMAN JESSETT also urged that there should not be too much hurry in removing fibroids; but when interference was necessary he thought it was easier and better to take away the whole uterus than to enucleate.

Mr. J. FURNEAUX JORDAN (Birmingham) asked how it was proposed to check hæmorrhage. In a case with multiple nodules he thought it impossible to bring the edges to the abdominal wound and also to bring the deep surfaces into apposition, and unless this could be done he thought hysterectomy was the easier operation.

Dr. HERBERT SNOW observed that the operation for the enucleation of *multiple* fibroids must stand or fall by its claim to conserve the child-bearing organs. What reason was there for thinking that a uterus so far diseased could resume its functions?

Dr. HEYWOOD SMITH was one of those who thought that hysterectomy was a better operation than enucleation in most cases; if enucleation were done the tincture of matico was a styptic which could be relied on. As regards pregnancy with fibroids, all depended on the position of the tumour; when in the fundus there was no reason why pregnancy should not end safely at term; but in the cervix there was considerable danger.

Mr. CHRISTOPHER MARTIN (Birmingham) said that the reduction of mortality had led many surgeons to operate unnecessarily. But granted a suitable case he thought that if there were more than one nodule enucleation was more risky than hysterectomy and the cure was not certain. He had lately to perform hysterectomy in a case in which a distinguished surgeon had performed enucleation five years previously; no doubt at the time there were no nodules left, yet after twelve months the symptoms began again necessitating the second operation.

Dr. C. H. F. ROUTH put in a plea for less heroic measures. He quoted with approval the practice of the late Mr. Baker Brown as illustrated by the case of a woman with three fibroids of the size of oranges projecting from the sides of the uterus into the vagina. He simply cut through them without trying to enucleate them and they disappeared. Modern surgeons would probably have done a more complete operation with no better results.

Dr. F. EDGE (Wolverhampton) remarked that while they

were anxious to preserve organs they were more anxious to preserve life and he thought the mortality of enucleation was twice as great as that of hysterectomy.

The PRESIDENT thought enucleation had been abandoned both here and on the continent. In the paper under discussion one case was reported as having died from the operation, but there were three post-mortem examinations and he thought they ought to look at the ultimate results.

Dr. ALEXANDER, in reply, thanked the Fellows for the way in which they had received his paper and for their frank criticisms. He did not advise operation for all cases of fibroids and he did not advise enucleation in every operative case, but he thought it would at least give them an alternative to hysterectomy, and that in being a non-mutilative operation it presented a marked advantage over total removal of the uterus.

The following card specimens were shown :—

Dr. MACNAUGHTON-JONES: Hæmorrhage into the Ovary and Cystic Ovary causing Dysmenorrhœa.

Mr. J. FURNEAUX JORDAN: Unruptured Tubal Gestation.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

AT a meeting of this society held in the out-patient room of the Leeds General Infirmary for the exhibition of cases of clinical interest,

Mr. LITTLEWOOD showed the following cases:—1. Intra-peritoneal Rupture of the Bladder, seen with Mr. W. A. Stott. The patient, a man, aged twenty-eight years, was operated on thirty-six hours after the injury. The abdomen was opened and three or four pints of urine were evacuated; there was some peritonitis. The rupture in the bladder was about one and a half inches long, in the middle line, terminating about the peritoneal reflexion; this was stitched up with 8 or 10 interrupted catgut sutures, including all the coats with the exception of the mucosa. The peritoneum was drained for forty-eight hours by means of a Bantock's tube. The patient passed urine six hours after the operation and no catheter was passed. The patient was up at the end of three weeks with the wound soundly healed. 2. Bullet Wound of the Sigmoid Flexure. The patient, a man, aged twenty years, was operated on six hours after the accident. An incision was made through the abdominal wall through the track of the bullet when the bullet was found to have entered the peritoneal cavity, perforated the sigmoid flexure, and lodged in the sub peritoneal tissues over the iliacus muscle. The bullet was extracted and the two wounds in the sigmoid flexure were stitched up by Lembert's sutures. The peritoneum was drained for forty-eight hours. The bowels were opened six days after the operation and the patient left the infirmary on March 14th with the wounds healed. 3. Ununited Fracture of the Femur, wired. A man, aged sixty-five years, had a spiral fracture through the middle of his right femur eleven weeks before the operation. The femur was wired on March 20th, 1897. The cause of non-union was a large piece of muscle between the fragments. He had now firm union and went about with a stick. 4. Excision of the Head of the Humerus for Old-Standing Dislocation. A man, aged forty-eight years, dislocated his left shoulder in September, 1897. Five attempts at reduction were made and the head of the humerus was excised on Nov. 15th, 1897. It was then found that the neck of the scapula had been fractured and the glenoid cavity was obliterated. The patient has now a useful limb. 5. Two cases of Thyroid Cysts removed by Symonds's Method. 6. Some cases of Joint Tuberculosis treated with Iodoform Injections.

Dr. TREVELYAN showed (1) six cases of Locomotor Ataxia, two complicated with aortic disease, one with optic atrophy, one of possible traumatic origin, and two undergoing exercise treatment; a photograph of two cases occurring in husband and wife was also shown; (2) a case of Infantile Hemiplegia with Fits and Disordered Movements; and (3) a case of Infantile Spastic Paraplegia with Fundus Changes, suggesting a possible syphilitic origin for the nervous disease.

Mr. WARD showed the following cases:—1. A boy, aged thirteen years, suffering from Ununited Fracture of the Left Tibia and Fibula with Skiagram. The original fracture occurred in 1889 and since then the patient had had the bones resected six times and wired on four occasions with a negative result. 2. A man, aged forty-one years, who had had Rodent Ulcer of the Orbit and Face excised, followed by two plastic operations, with a series of Photographs showing the various stages. The duration of the disease was ten years, the patient having undergone five previous operations. 3. Three men, aged thirty-four, fifty-five, and forty-seven years respectively, who had had proctectomy performed for Malignant Disease of the Rectum, intra-peritoneal lumbar colotomy having been performed prior to the major operation in each case. There had been no return of the disease and the patients were gaining weight and following their employment.

Dr. CHURTON showed a woman, aged thirty-five years, who while under treatment for chronic rheumatism and mitral disease contracted Syphilis. A secondary rash had appeared three weeks ago. After ordinary treatment for a fortnight all medicine by the mouth was stopped and 4 minims of "grey oil" were injected into a gluteal muscle. The rash, which had been spreading over the face and back, although fading on the chest, was now rapidly fading everywhere. In several cases of visceral syphilis this method had been found convenient; in none had there been any marked pain or other undesirable result.

Other cases and specimens shown were :—

Dr. CHURTON: A New Method of Testing for Indican.

Dr. TREVELYAN: (1) A case of Syphilis of the Larynx, Mouth, and Nose; and (2) a case of Double Abductor Paralysis of the Larynx.

Mr. MAYO ROBSON: (1) Needle in the Knee-joint removed by operation; (2) Pyonephrosis; Renal Calculus; Nephrolithotomy; (3) two cases of Ascites apparently cured by Laparotomy; (4) Gluteal Aneurysm; Ligature of the Common Iliac Artery; (5) Ovarian Cyst with Tubercular Peritonitis; Ovariotomy; and (6) Gallstone Impacted at the Papilla of the Common Duct; Duodeno-choledochotomy.

Dr. BARRS: (1) A case of Diphtheria treated by Antitoxin and Tracheotomy in which membranous casts of the trachea were coughed up; and (2) a series of Clinical Photographs shown by the lantern.

Mr. H. LITTLEWOOD: Lumbar Nephrectomy for Malignant Disease.

Mr. WARD: Sarcoma of the Fibula.

Dr. HELLIER: (1) A case of Spastic Paraplegia; and (2) a case of Extreme Hydrocephalus.

Mr. W. H. BROWN: (1) Carcinoma of the Sacrum in a Child; (2) Fracture of the Acromial End of the Clavicle; (3) Abdominal Swellings in an Infant; and (4) two cases of Compound Depressed Fracture of the Skull not operated upon.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases.—Osteo-Arthritis.—Surgical Treatment of Pyloric Obstruction.

A MEETING of this society was held on April 14th, Dr. MACFIE CAMPBELL, the President, being in the chair.

Dr. G. STOPFORD TAYLOR showed a fair-complexioned girl, six years of age, suffering from an attack of Urticaria of one month's duration, commencing shortly after an attack of measles. White wheals of the size of a bean appeared upon the cheeks, buttocks, legs, and forearms; those on the cheeks and arms became rapidly pigmented—urticaria pigmentosa; and those on the buttocks became hæmorrhagic—urticaria hæmorrhagica. The eruption was rapidly subsiding under an anti-scorbutic diet and lime juice. He also showed a case of Purpura as a contrast case.

Dr. C. MACALISTER exhibited lantern slides of a post-mortem examination on a case of Complete Transposition of the Viscera.—Dr. GORDON GULLAN mentioned a similar case that occurred in the Royal Infirmary under the care of Dr. Caton; the transposition was complete and the patient had been left-handed; no distinct difference was found in the development of the cerebral convolutions of the two sides.

Dr. C. MACALISTER also read a note on Osteo-arthritis, illustrated by a series of lantern slides showing the several varieties. He had seen good results follow the administration of ox blood dried in vacuo and given in the form of tabloids.—Dr. BRADSHAW alluded to the views of Bannatyne and Wohlmann that osteo-arthritis was due to a specific micro-organism which they had found in the synovial membrane and fluid of affected joints. Acting on this he had

found benefit from the administration of creasote and thought that the good results following the ox blood treatment were quite consistent with the microbic theory, as the blood might contain some antidote to the toxins secreted by the organisms.—Dr. CARTER, Dr. GRÜNBAUM, Mr. RAW, and Dr. WARRINGTON spoke.

Mr. PAUL read a paper on the Surgical Treatment of Pyloric Obstruction, with an account of 20 cases and of a new method of performing Gastro-enterostomy. The cases consisted of 3 of Loreta's operation, 5 of pyloroplasty, 2 of pylorectomy, and 10 of gastro-enterostomy. The heaviest mortality occurred in the last class. He thought Loreta's operation was now superseded by the much better pyloroplasty. Pylorectomy had only a limited application; the cases did not come under surgical treatment sufficiently early. For gastro-enterostomy he considered that no thoroughly satisfactory operation had yet been devised and suggested the following. An incision is made through the musculo-peritoneal coats of the bowel, which are then reflected with a blunt dissector and the denuded submucosa rubbed with a stick of zinc chloride. The stomach is next treated in the same way except that the outer coats are excised and not simply reflected. A continuous suture is now run around the areas operated upon connecting the stomach and bowel and a few Halstead sutures are added when necessary. The results of experiments on dogs by this method of anastomosis were given; anastomosis occurred in about twenty-four hours and a good opening was produced.—Mr. RUSHTON PARKER observed that Mr. Paul had dealt very ably with a somewhat extensive and many-sided subject. He would not attempt to go into more than a few points raised, having at a recent meeting expressed his own views in relation to several cases in which he had himself performed pyloroplasty, not only in cicatricial stenosis but in cases of malignant disease. It was clear that pyloroplasty must be of limited application in malignant disease and that gastro-enterostomy was the operation most likely concerned. At the same time Mr. Parker's view was that the scope for ingenuity, and consequently interest, offered by malignant disease fell far short of that deserved by other cases and he had frequently refrained from extensive operation of quite possible success on that account.—Dr. CARTER and Dr. ROSS joined in the discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimen.—Some Points in the Etiology of Typhoid Fever.

A MEETING of this society was held on March 31st, the President, Dr. SINCLAIR WHITE, being in the chair.

Dr. ARTHUR HALL showed a case of Xerostomia in a woman, aged forty-nine years. The condition had lasted for a year and had been quite unrelieved by any form of treatment.

Mr. ARCHIBALD CUFF showed (1) a case of Resection of the Astragalus; and (2) a patient who had been rapidly relieved of a Psoas Abscess.

Mr. PRIESTLEY showed a specimen of Aneurysm of the Abdominal Aorta.

Dr. ROBERTSON read a paper on Some Points in the Etiology of Typhoid Fever. He pointed out that direct infection accounted for a much larger number of cases than was generally supposed—probably about as many as 10 per cent. of the total number of cases were due to this cause. A great deal of attention had very properly been given to the prevention of water-borne typhoid fever. The much more difficult subject of endemic typhoid fever has not received the attention which its importance seemed to merit. Probably as much as from 80 to 85 per cent. of the cases of typhoid fever which occurred in this country were not water-borne and were not due to direct infection. Dr. Robertson related his experiments, which went to show that the typhoid organisms could live for very long periods in the soil and that it appeared to be essential for their growth that they should be fed with fresh supplies of organic matter at intervals. These conditions were just those found in the unsanitary conditions which were most often claimed to have produced the diseases—viz., gross soil pollution. From such areas the organism was easily spread by wind into the food-supplies of persons living in houses near. Statistical evidence went to show that persons living in areas where soil pollution occurred were much more frequently attacked than persons in clean areas. In large public institutions endemic typhoid fever was practically unknown.

The PRESIDENT, Dr. JAMES MARTIN, Dr. F. H. WADDY, Dr. WILKINSON, Dr. LEONARD GILES, Dr. ARTHUR HALL, and Dr. MEREDITH RICHARDS joined in the discussion.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Adherent Placenta.

A MEETING of the above society was held on April 6th, Dr. CATTLE, President, being in the chair.

The PRESIDENT reported the result of the deputation to the Watch Committee concerning the question of the delivery of lectures on sexual subjects in public.

Dr. HEELIS read a paper on Adherent Placenta. He ascribed as causes of it previous endometritis and in primiparæ the condition producing membranous dysmenorrhœa. Cases in point were cited. The natural removal of retained adherent placenta was carried out by decidual cells playing the part of osteoclasts and phagocytes. The dangers of retained placenta are hæmorrhage and sepsis, either occurring after abortion or at full term. Small portions of adherent placenta after an abortion may set up severe hæmorrhage, but large portions will not necessarily cause septic mischief. The treatment recommended was the complete evacuation of the uterine contents, curetting if necessary, and subsequent injection of iodoform emulsion and plugging with iodoform gauze. An operation for retained uterine contents should be carried out, however, under the strictest antiseptic precautions so as to prevent consequent septic troubles. A mixture of quinine, ergot, and digitalis administered after the operation is of some value to secure continual contraction of the uterus.—A discussion followed in which Dr. CATTLE, Dr. HANDFORD, Dr. WOOD, and Dr. BOLTON took part and Dr. HEELIS replied.

Dr. HANDFORD showed a microscopical specimen of Urine containing the Bilharzia Hæmatobia.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Isolation after Diphtheria.—Epidemic of Influenza in a School.—Development of the Embryo.

THE seventh meeting of the session of this society was held in the Medical Library of University College on April 13th.

Mr. C. A. MORTON showed a patient from whom the upper end of the Fibia was Removed for Sarcoma and who was shown at a meeting of the society a year ago.

Mr. F. LACE showed a specimen (with microscopic slides) of Duct Papilloma of the Breast.—Dr. AUST LAWRENCE spoke on the subject.

Mr. PAUL BUSH showed a large Tumour of the Vertebræ which had all the appearance of carcinoma under microscopic examination; it occurred in a young girl and at the post-mortem examination no other primary growth could be found.—Mr. MUNRO SMITH discussed the pathology of the specimen which he considered was a true carcinoma.

Mr. PAUL BUSH also showed a Tumour of the Ovary weighing 4½ lb. which he had successfully removed during an acute attack of peritonitis due to twisting of the pedicle. The tumour had been noticed for about ten years. The microscopic slides showed it to be a fibromyoma undergoing well-marked myxomatous degenerations.—Mr. MUNRO SMITH, Dr. P. W. WILLIAMS, Dr. STACK, and Dr. AUST LAWRENCE discussed the case.

Dr. J. O. SYMES showed numerous Surface Plate Cultures from Vaccine Lymphs.—Mr. H. WATHEN and Mr. EWENS remarked on the subject of human and vaccine lymphs.

Dr. T. FISHER showed a series of Pathological Specimens recently added to the Bristol Royal Infirmary Museum.

Dr. B. ROGERS read a paper on Isolation after Diphtheria in which he advocated a more frequent and regular bacteriological investigation of the discharges of those recovering.—A long discussion on the period of isolation required after

this disease followed, in which Dr. MICHELL CLARKE, Dr. P. W. WILLIAMS, Mr. H. WATHEN, Dr. SYMES, Dr. ELLIOTT, Dr. SKERRITT, Dr. PARKER, and Dr. SHINGLETON SMITH took part.

Mr. J. TAYLOR read a paper on an Epidemic of Influenza in a School; this was illustrated by lantern slides.—Dr. SKERRITT and Mr. H. WATHEN discussed the paper.

Mr. MUNRO SMITH gave an interesting demonstration of the Development of the Embryo, illustrated by numerous beautiful micro-photographs, which were thrown on the screen by the oxy-hydrogen light.

FORFARSHIRE MEDICAL ASSOCIATION.

Exhibition of Cases and Specimens.—Tropical Abscess of the Liver.—Injury to the Lower Lumbar Vertebræ.

A MEETING of this society was held at University College, Dundee, on April 1st, Dr. A. CAMPBELL, President, being in the chair.

Dr. MACEWAN showed a case of Reproduction of the Humerus after Operation for Acute Necrosis and also a case after Estlander's operation.

Mr. D. M. GREIG showed a case of Congenital Malformation of the Anus rectified by operation; the rectum opened in front of the posterior fourchette.

Mr. GREIG also showed four Abdominal Cases: (1) a case of recovery after operation for Volvulus; (2) a case after operation for Appendicitis with Retro-cæcal Abscess; (3) a case after cœliotomy for Abdominal Pain; and (4) a case of Incurable Malignant Tumour in the Abdomen in which the tumour had diminished somewhat and the patient had put on weight.

Dr. BUIST showed a series of Specimens treated by Tores' Method.

The PRESIDENT read notes of a case of Tropical Abscess of the Liver. The patient, a woman, aged fifty-one years, had spent eighteen years in Calcutta enjoying good health till she had a severe attack of malarial fever. Her condition showing no improvement after three months she was therefore ordered home. On Aug. 17th, 1897, the patient was found to be much exhausted, the temperature was 103° F., and the liver was enlarged upwards, there being no pain, no diarrhœa, and no jaundice, but sweats and chilliness. Towards the end of August the patient had a sharp attack of perihepatitis. Aspiration was done at first without success, but on Sept. 18th three pints of purulent fluid were withdrawn. The dulness, which had after this tapping diminished, again increased. On Sept. 25th a portion of the seventh rib was excised in the right nipple line, the liver was incised, and the abscess cavity was evacuated. A drain was inserted into the most dependent part between the eighth and ninth ribs in the posterior axillary line. The drain was removed in December and the patient is now as well as ever.—Dr. MACEWAN spoke of a case he had had under his care.—Dr. MACKIE WHYTE referred to the absence of fluctuation and also to the absence of dysentery in the case read.

Dr. PIRIE read notes on a Simple Method of Clinical Bacteriology and showed several micro-photographs and also tubes of cultivations.

Dr. FOGGIE read notes of a case of a man who had received an Injury to the Lower Lumbar Vertebræ by a fall from a scaffolding. Paraplegia from the hips downwards had existed at first, but the various movements at the hip and the knee-joints were soon restored, while the initial retention of urine and the constipation after passing through a stage of incontinence showed now a modified control. Muscular movements below the knees and reaction to the faradaic current were still absent. Neither the knee-jerks nor plantar reflexes had as yet returned. There was well-defined total anæsthesia around the anus and in front and also lower down over both heels. Partial anæsthesia existed over all the skin below the knees except on the inner sides and was connected by a narrow band running up the back of the thighs, with upper totally anæsthetic area. Thermo-anæsthesia was practically co-extensive. Vaso-motor and trophic changes were present. The primary lesion had affected the lumbar region of the cord or its roots as high as the third segment or root, but the permanent lesion had been almost limited to the sacral region of the cord or its roots. Possibly the injury was one of the cauda equina.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Cases and Specimens.—Osseous Union of Transverse Fracture of the Patella.

A MEETING of this section was held on March 25th, Dr. J. M. PURSER, the President, being in the chair.

Dr. E. H. BENNETT exhibited an example of Rupture of the Duodenum from the kick of a horse. In the absence of any definite symptoms an exploratory laparotomy was performed without any lesion being discovered. At the post-mortem examination it was found that the portion of the duodenum which lay against the spine and outside the peritoneum had been ruptured and that the intestinal contents had escaped along the spine downwards as far as the pelvis.

Dr. J. W. MOORE showed a specimen of Cancer of the Œsophagus and Perforation of the Right Subclavian Artery by a Secondary Growth. The patient was a man, aged fifty-six years, who died from torrential hæmorrhage, after suffering from dysphagia for seven or eight months and subsequently from laryngeal paralysis due to pressure on the left recurrent laryngeal nerve, from fœtid sputum and breath, and from other pressure symptoms caused by a squamous cancer which involved the œsophagus at the level of one inch above the diaphragm; the immediate cause of death was hæmorrhage, due to perforation of the right subclavian artery by a secondary cancerous tumour.

Mr. WHEELER exhibited a patient who had been trephined for a Depressed Fracture of the Skull caused by a fall from the top of a tramcar. His symptoms were profound coma, complete paralysis, stertorous respiration, and laboured and slow pulse (50 per minute). The surface of his body was warm and perspiring, both his pupils were dilated, his reflexes were lost, and his fæces and urine were retained; there was no hæmorrhage from his ear, mouth, or nose. An extensive depression could be easily detected upon the left side of his head in front of the parietal eminence. A large triangular piece of bone was removed as were two smaller pieces with several spicula. From the superior portion of this large triangular piece of bone the superior longitudinal sinus had to be separated. There was considerable hæmorrhage from a large cerebral vessel as well as from wounds in the dura mater. Ten minutes after the operation the patient conversed with his master. He is now quite recovered except for the loss of sight in his left eye.

Mr. WHEELER also showed specimens of extensive Multiple Rupture of the Liver and Kidney. The patient was a child, aged six years, who was run over by a cart and was admitted to the City of Dublin Hospital on March 10th at 3 30 P.M. apparently with little the matter, as the child ran about the accident ward. There was no external mark. At 4·15 P.M. the child, lying in the bed, became obviously ill; shortly afterwards it exhibited all the signs of collapse, and three hours later, at 7.10 P.M., the patient died.

Mr. WHEELER also showed a large sarcomatous tumour originating in the sphenoid bone removed from a man, aged twenty-five years. Mr. Wheeler trephined this patient by his own operation in December, 1897, opening the mastoid cells and the tympanum, and exposing at the upper arc of the trephine circle the dura mater, which allowed the temporal lobe to be explored. He recovered rapidly and progressed to convalescence, feeling much relieved from the pain. The discharge ceased, there was less contraction of his masseter muscles, and the pains in his right face were very much lessened, but the facial paralysis remained unaltered. In February, 1898, the pain again troubled him and, in fact, returned as before the operation just described. His masseter muscles again became rigid and contracted and he now complained of pain in the temporal region anterior to, and on a level with, the superior margin of his ear. He was trephined (by Mr. Wheeler) over the seat of the pain in March. A careful examination was followed by a negative result; the man expressed himself much relieved from the pain, which had been acute; he lived until March 8th and apparently died from pressure on the region of the medulla. On post-mortem examination it was found that the tumour was of vast extent, pressing into the ethmoid bone in front and into the pterygoid regions on the right side; behind it involved the basilar process of the occipital bone and the occipito-atlantoid joints. There was no eye trouble,

although the third, fourth, fifth, and sixth nerves passed through the tumour.

Dr. JOHN KNOTT read notes of a case of complete Osseous Union of Transverse Fracture of the Patella.

Reviews and Notices of Books.

Epidemic Diphtheria; a Research on the Origin and Spread of the Disease from an International Standpoint. By ARTHUR NEWSHOLME, M.D., M.R.C.P. Lond. London: Swan Sonnenschein and Co. 1898. Price 7*s.* 6*d.* net.

THIS is a valuable contribution to the epidemiology of a disease which has apparently become increasingly prevalent in populous places where half a century ago it was practically unknown. The method adopted by the author to determine the extent of its diffusion consists in the collation from all quarters of the globe of mortality statistics of diphtheria, which he presents in the form of charts all drawn to the same scale and representing the death-rate per 100,000 living in each place for each of the series of years during which such statistics are available. He thereby dispenses with columns of figures and enables the reader to perceive at a glance the actual and comparative prevalence of diphtheria in a large number of centres of observation. The application of the study of mortality statistics to the science of epidemiology must become increasingly valuable, since year by year these returns enable the survey to be widened. For although, strictly speaking, the number of deaths from an infectious disease do not invariably concord with actual prevalence, owing to variations in fatality and virulence in different places and at different periods (and, it may be added, also the effects of treatment, since the introduction of antitoxic serum has admittedly diminished the fatality of diphtheria), yet there is on the whole a sufficient degree of concordance to justify inferences as to prevalence to be drawn on a wide scale from mortality statistics. Until notification of diseases becomes universal, and has been in force for a long series of years, it would be impossible to obtain any other standard of comparison than that which is derived from the death-rate. In eleven chapters, each profusely illustrated by the charts referred to, Dr. Newsholme records the statistical returns of diphtheria (sometimes inclusive of "croup," sometimes differentiated from this form of the disease) of many of the important cities of the United States and Canada; of England and Wales, Scotland and Ireland; of France, Italy, Holland and Belgium; of Germany, Austro-Hungary and Russia; of Scandinavia; of Africa and Asia; of Australia and New Zealand. It is indeed a valuable collection, one which encourages the hope, in these days of international scientific congresses, that some system of international registration of disease may in due time be established. It will be found that the periods over which the records extend vary considerably in the different localities, but it is evident from them all that diphtheria is a disease which is endemic in all cities, and that there is not one in which the mean death-rate is not from time to time so greatly exceeded as to mark such years as epidemic years, the duration of such "epidemics" being as variable in extent as their virulence is in severity. It is clear, too, that there is a tendency in any given place for epidemics to recur in cycles, and that at certain periods even the increase is so general as to justify the phrase "pandemic" to be applied to the widespread manifestations. Another striking fact is the manner in which in contiguous towns an epidemic year in one is succeeded in the following year by an epidemic in another; whilst to take the instance of London—a vast congeries of districts—the manner in which the present epidemic that culminated in 1893 advanced from one district to another is most suggestive. All this and more is admirably illustrated and clearly expounded by Dr. Newsholme, and if we refrain from citing figures it is only because the multiplicity of instances which fill his pages renders it impossible to do justice to his work. Nevertheless it may be said that the degree to which diphtheria prevails in this country is strikingly less than its prevalence in America or on the continent of Europe. Nor are the epidemic years accompanied by such a great increase in mortality as appears in the latter. It may be noted in passing that of all the countries investigated Ireland is the most favoured in respect to the small amount of diphtheria to which it is subject.

A very interesting subject of study is the manner in which the disease diphtheria came to be recognised as a distinct entity, for although in the twelfth chapter Dr. Newsholme traces its chronology back to remote times it was not until 1855 that the term appeared in the death returns of England and Wales and not until 1859 that it was registered in London. There can be no question at all that "croup," which figures largely in the death roll of the fourth and fifth decades of the century, that "cynanche maligna," and probably also many cases returned as "scarlet fever," were really what are now recognised as diphtheria. Indeed, Dr. Newsholme points out that the striking rise in the "croup" death-rate in London in 1847, coinciding as it did with an epidemic of influenza, was probably due to an epidemic of diphtheria, whilst the enormous rise in the deaths from diphtheria in England and Wales during 1858 and 1859 is led up to by an increase dating from 1855 of the allied affections. At the same time, with all allowances for changes in nomenclature, it must be admitted that diphtheria has become more and more of an endemic disease since the establishment of freer intercourse and facilities of communication between cities, whilst factors for the epidemic cycles that recur with such variable and sometimes marked frequency may be found in the facilities for personal infection of susceptible subjects, such as is afforded by school attendance, although Dr. Newsholme would by no means regard the latter as a main cause of epidemics. He takes a wider view of the subject, as an epidemiologist should do, and it is instructive, if somewhat discouraging, to find that perhaps the chief influences of the prevalence of this dreaded disease are beyond human control. He shows by careful research that diphtheria prevails most in dry seasons, that in nearly every place an epidemic is preceded by a series of years in which the rainfall has been deficient and the ground-water has therefore become of a low level, and that there is less diphtheria in districts where the rainfall is excessive—e.g., Ireland—than where it is scanty. Hence the inference that the diphtheria bacillus is a saprophyte as well as a parasite and that the conditions favouring its multiplication and perhaps its virulence are mainly those of dryness of soil. Of course such a conclusion does not get rid of the element of personal infection, to which, indeed, the *spread* of the disease is mainly due, but it does suggest that the recurrence of periods of excessive prevalence may be determined by an increase in amount and virulence—whereby the numbers of the "susceptible" are also increased—of the diphtherial microbe. In his closing remarks Dr. Newsholme says that such a conclusion should not depress us, since we must recognise that diphtheria is spread chiefly by personal infection, which is "immensely more potent in epidemic than in inter-epidemic years—a fact which should lead to redoubled efforts to prevent personal infection during such epidemic periods rather than to a fatalistic inertia. Similarly redoubled efforts are required to prevent ground-air from gaining admission into houses and to render more wholesome the soil in districts in which diphtheria has become endemic." We take leave of this book by gratefully acknowledging the service which its

author has rendered, at what must have been the expenditure of no little labour, to epidemiological science, and we may express the hope that similar studies of other specific diseases may come to advance our knowledge of the problems which they present.

Scientific Memoirs by Medical Officers of the Army in India. Edited by Surgeon-Major-General J. CLEGHORN, M.D. St. And., C.S.I., Director-General of the Indian Medical Service. Part X. Calcutta: Office of the Superintendent of Government Printing, India. 1897. Price 4 rupees.

WE are always glad to receive these scientific memoirs because the articles which they contain, in addition to exhibiting a strictly scientific spirit, and a reliable, painstaking method of work, are a mark of the scientific activity that prevails among the members of an important medical service. We congratulate that service on possessing the writers of the various papers in Part X. of this series. The first is a contribution by Brigade-Surgeon-Lieutenant-Colonel D. D. Cunningham, C.I.E., F.R.S., on Choleraic and other Commas, on the Influence of Certain Conditions in Determining Morphological Variations in Vibrionic Organisms. The second is, Notes on the Malarial Parasite as observed in the Blood during Life and in the Tissues Post Mortem at Lahore, Punjab, by Surgeon-Captain Murray, M.B. The third is on the Influence of Variations of the Ground-water Level on the Prevalence of Malarial Fevers, by Surgeon-Captain Leonard Rogers, M.B., B.S. Lond., F.R.C.S. Eng., I.M.S. This excellent paper has been already published and noticed in THE LANCET of March 12th, 1898, p. 706. The fourth and fifth papers are by Brigade-Surgeon-Lieutenant-Colonel D. D. Cunningham, C.I.E., F.R.S.; one is a Report on the Results of Experiments on the Action of Various Reported Antidotes to Snake-venom conducted during the Season 1895-96; the other on Certain Diseases of Fungal and Algal Origin Affecting Economic Plants in India. Those who are interested in the bacteriological studies of cholera and the comma bacillus and other micro-organisms connected with that disease will do well to peruse the results of the latest researches and observations of Professor D. D. Cunningham recorded in his article in the present part of this series of Scientific Memoirs. We must not forget to add that the plates and diagrams illustrating the different papers are very good.

Yellow Fever in the West Indies. By IZETT ANDERSON, M.D. Edin., Extraordinary Member of the Royal Medical Society of Edinburgh; Honorary Member of the Institute of Jamaica; formerly Resident Surgeon of the Colonial and Seamen's Hospital, Georgetown, British Guiana, &c., &c. London: H. K. Lewis. 1898. Price 3*s.* 6*d.*

THIS little treatise embodies the results of the author's experience after thirty-four years' hard professional work in the West Indies and previously in a Government appointment in a large hospital in British Guiana. Dr. Anderson in his preface gratefully alludes to the circumstance that he was fortunate in having had practical instruction in yellow fever from able and experienced men before he had to treat his first cases, and he refers to the difficulties with which the inexperienced practitioner has to contend who is called upon to treat the disease without any previous clinical knowledge of it. The author's remarks in this respect are not only applicable to yellow fever but to diseases of tropical and subtropical climates generally. We are glad to see that efforts are being made in this country to remedy this deficiency in medical education, and that lecturers on these diseases have been appointed at some of the metropolitan hospitals and medical schools, as at St. George's, St. Mary's, and the Middlesex. The book contains, as might be expected, but little on the pathology and bacteriology of yellow fever; it consists mainly of reminiscences of a clinical and therapeutical nature and of impressions derived from the author's practical acquaintance with that disease. In the first chapter the health conditions of the West Indies formerly and at the present time are briefly described and they furnish a striking testimony to the prophylactic results of progressive medical and sanitary work. The change is a very remarkable one, for formerly, owing to a disregard of obvious insanitary conditions and considerations of personal hygiene and defective medical knowledge, the mortality among British troops and Europeans generally was enormous, whereas under improved sanitation, improved habits of life, a clearer appreciation of the predisposing causes of disease, and better methods of treatment the death-rate has been steadily diminishing, until the West Indies may now be reckoned as among the most healthy of our British colonies, whither, as we know, tourists and persons in delicate health often nowadays proceed as a winter resort. Practically speaking, we may say that about the best thing to do in the event of an outbreak of yellow fever on shipboard is to put to sea at once and run towards the north. Chapter II. deals briefly with the geographical distribution of the disease and its causes, reference being made incidentally to the bacteriological observations of several writers, and to those of Sanarelli of Monte Video and Havelburg of Rio Janeiro in particular, regarding the existence of a specific organism as the essential cause of yellow fever. In Chapter III. the susceptibility to attack is dealt with and it is pointed out that while natives and negroes have a relatively small susceptibility to yellow fever they are nevertheless occasionally attacked by it. In Chapters IV. and V. the symptoms and course of the disease and the state of the urine in yellow fever are discussed; the observations regarding the latter point are valuable. The remaining chapters deal with the clinical phenomena, mixed forms, diagnosis, and treatment of the disease, and the concluding one briefly discusses the contentious question, so long and hotly disputed, as to whether yellow fever is contagious or not. The author is, on the whole, a non-contagionist, and as regards fomites as a means of its spread he quotes with approval the views of Professor William Bailey, of Louisville, Kentucky, on the "Etiology of Yellow Fever," published in THE LANCET of Sept. 6th, 1879. While Dr. Izett Anderson cannot be said to have added anything particularly new in regard to our knowledge of yellow fever or its treatment, his small volume may be accepted as, at any rate, an honest record of personal experience in regard to a disease which he had unusual opportunities of practically studying during his professional life in British Guiana and the West Indies.

JOURNALS, REVIEWS, &c.

The Practitioner for April is a good number. The editorial "Month" contains some good stories about the late Sir Richard Quain and Sir William Jenner. We are sorry to see, however, in one of these stories the solecism "and which" used without a preceding relative. There is an admirable letter quoted from a Philadelphian physician addressed to a Philadelphian paper on the enormity of inserting advertisements of quack medicines, abortionist preparations, and the like. Mr. Ballance reports a case of removal of a Ruptured Spleen followed by Recovery, and Dr. C. E. Michael has an interesting paper on the Complications attending the Serum Treatment of Diphtheria. Other papers are by Dr. Rose Bradford, on a Form of Bright's Disease occurring in Young Women; and by Dr. E. Maddox on Circumlental Photography. The Medico-Literary Causerie deals with the Shrine of Asklepios at Epidauros. A new feature of the journal is a

Literary Supplement, which will be issued in future every three months.

West London Medical Journal.—The opening article is a paper on the Transmission and Dissemination of Cancer, with which Mr. C. A. Ballance introduced a discussion on the subject at the West London Medical Society. It contains a summary of the experiments made by himself and Mr. Shattock in the hope of cultivating parasites, either protophyta or protozoa, from malignant new growths. All the results were negative, and all endeavours to inoculate lower animals with cancer were also unsuccessful, but Mr. Ballance nevertheless believes that the living nature of the virus of cancer will eventually be demonstrated. In the "Mirror of Practice" Dr. Seymour Taylor records an interesting case of successful treatment of the morphia habit.

Heilstätten-Korrespondenz (Sanatorium News).—The current number contains a variety of miscellaneous information relative to establishments for the treatment of phthisical patients. The opening paragraph is an extract from an address by Dr. Dettweiler of the sanatorium at Falkenstein, the general purport of his argument being that it is a mistake to suppose that high altitudes are specially beneficial in the treatment of phthisis. In another part of the paper it is stated that the late Mr. Adolf Machlup has bequeathed 217,000 florins to the Hungarian Red Cross Society for the erection of a sanatorium.

Mercy and Truth.—Dr. A. Cook publishes a continuation of the account of his work among the wounded in Uganda. A report written by a native medical practitioner named Ting Sin King, who works under the Rev. J. Martin at Kucheng, in China, is printed in the original Chinese, together with a translation.

The Journal of Physiology. Edited by MICHAEL FOSTER, M.D. Lond., and J. N. LANGLEY, Sc.D. Vol. xxii., No. 3. London: C. J. Clay and Sons. Price 6*s.*—This part contains the following articles: 1. G. N. Stewart, Professor of Physiology in the Western Reserve University, Cleveland, U.S.A.: Researches on the Circulation Time and on the Influences which Affect it. Part 4. The Output of the Heart. He estimates it at about 80 c c. or about 4½ oz. per heart-beat with a pulse-rate of 72, but finds that the output per second may vary considerably even when the pulse-rate is approximately constant, whilst on the other hand the output per second may remain approximately constant while the pulse-rate undergoes considerable variation. 2. F. Gowland Hopkins and Francis W. Brook: On Halogen Derivates from Proteids. 3. S. J. Meltzer, M.D., of New York: On the Paths of Absorption from the Peritoneal Cavity. He considers that his experiments prove in opposition to those of Messrs. Starling and Tubby that absorption takes place by the lymphatics in preference to the blood-vessels. 4. Wakelin Barratt, M.D. Lond.: On the Elimination of Water and of Carbon Dioxide from inflamed Skin. Dr. Barratt found that in dry dermatitis caused by carbolic acid the quantity of both H_2O and CO_2 excreted is at first decreased, the former largely, the latter slightly. In the case of CO_2 the quantity excreted seems subsequently to be rather increased. 5. J. N. Langley: On the Regeneration of Pre-ganglionic and of Post-ganglionic Visceral Nerve Fibres. The majority of the fibres regenerate within a month of the section; the return of function begins as early as from the eighth to the twelfth day. 6. John Haldane, M.D. Edin., and J. Lorrain Smith, M.D. Edin.: On the Absorption of Oxygen by the Lungs.

The Phonographic Record for April combines with an entertaining paper on the Light Side of Medicine instruction in the shape of phonographic notes, a history of some medical words, and a plea for the use of phosphorus by Dr. Lundie. We are told that many phosphorus pills on the market having undergone oxidation are inert, but that when a pill of unchanged phosphorus can be procured good results have followed its use in cases where a nerve tonic is required and strychnine is too stimulating, sleeplessness and hunger being the indications for its use. Dr. Gray has resigned the treasurership of the Society of Medical Phonographers and Mr. Norman Porritt takes his place.

New Inventions.

A NEW APPARATUS FOR MEASURING THE HEIGHT OF PATIENTS.

MESSRS. MAW, SON, AND THOMPSON of Aldersgate-street have just submitted to us a new and very convenient apparatus for measuring the height of patients. It consists essentially of the usual horizontal rod sliding on a graduated standard which is attached by hinged brackets of stout brass to a polished walnut-wood panel about 3 ft. 6 in. in length. This panel is fastened by screws or otherwise to the back of the consulting-room door or to any suitable part of the wall. The object of the revolving brackets is to permit the horizontal rod when not in use to be turned to one side out of the way flat against the door or wall. The graduations of the rod extend from 4 ft. to 7 ft. The total weight of the apparatus is only a few pounds as there is no pedestal. The price is one guinea.

THE BRITISH PHARMACOPŒIA.

II.

IN THE LANCET of April 16th we gave a general summary of the changes made by the General Medical Council in the new British Pharmacopœia and we printed a list of the drugs and preparations omitted and also a list of the new drugs and preparations appearing for the first time in their official position.

A study of these lists will convince the thoughtful reader of the great care and thoroughness shown in the recent revision, and comparing the changes with those made upon former occasions he cannot fail to observe how bold and radical has been the aim of the new committee of the Council entrusted with the work.

It cannot be denied that in many respects our national Pharmacopœia was far from being a credit to British medicine and it was held by some teachers and authorities that each revision left matters in some respects in a worse position than before. This was notably the case with the 1885 volume. The revisers upon that occasion introduced a host of comparatively worthless preparations and weighted the book with them to such an extent that the practitioner was seriously embarrassed in prescribing and the student found his task of learning the subject of materia medica made more irksome than ever. This was mainly owing to the fact that little attempt was made towards uniformity in strength or dosage and no serious attempt was made to eliminate the great mass of worthless agents and obsolete preparations. Indeed, many of the new additions of that period were quite as objectionable as the ancient cumberers of the ground which had discredited the 1867 volume.

A glance at the following figures will prove this. Thus in 1885 the list of additions numbered no less than 114 new drugs or preparations, whilst the omissions only numbered all told 22. There is a verdict passed upon these additions which possibly may have never occurred to the minds of the members of the General Medical Council or of the revising committee and it proves how superficially the work of revision had been carried on up to the present attempt. It will be found that the present revisers have now rejected over 30 of these additions or supposed improvements and made important changes in many of the remainder. Indeed, some of the additions made at the comparatively recent date of 1890

have been now banished to obscurity—i.e., syr. ferri subchlor. and liq. morph. sulph.

It was therefore evident that things were drifting into chaos and confusion and a revision upon the old lines would have probably made the British Pharmacopœia a dead letter. It is with a feeling of great relief that we study the new volume, for it is evident that the new committee have carried out their work in an entirely different spirit and they deserve the gratitude of the entire profession. We offer them our hearty congratulations upon the result of their labour nor do we propose to qualify our praise by pointing out faults and blemishes still remaining. It is our intention to point out rather how the new changes will affect the practitioner and aid him in his struggle against difficulties in his daily work. At the same time we may be permitted to offer suggestions which will be of value as indicating how further progress may be achieved in making the British Pharmacopœia more valuable to him. At the outset it will be apparent that the committee have departed from the old policy of crowding in new preparations without making room for them. As we pointed out in THE LANCET of April 16th the book is of the same size as before, but if we exclude the appendices and index it is much reduced when compared with the size of the last issue. This is explained by the fact that the additions number only 80, while the omissions reach 188, as against 22 made by the 1885 revisers.

When the present revision was in the air two years ago it was urged by several writers that the British Pharmacopœia should be so altered as to be made more attractive and useful to practitioners. It is a strange and even startling fact that only a small percentage of medical men ever see even the outside of the volume. We know also that the student of medicine seldom has an introduction to it except through the text-books on materia medica. This is a condition of matters which should not exist and certainly some means should be employed to alter it. The practitioner when interrogated about it states that the book is of no use to him: he prefers to buy a text-book which embodies all that it contains and which gives him much more assistance about dosage, &c.

It may be worth while to look at the new volume from this standpoint and see if it will be likely to tempt the prescriber to add it to his shelf. One vital alteration has been made which renders the volume of much less assistance to the busy medical man. Formerly under the heading of each drug was printed a complete list of its preparations and their strengths, together with a list of every preparation into which it entered, though the preparation was called by a different name. At a glance if the practitioner consulted the volume he would see everything he required, now he must look at the drug under its heading and then turn to a very elaborate and most carefully compiled index, from which he must again turn to the different preparations. If the student wishes to find into what preparation a drug such as acetic acid enters he may spend some days before finding them all out. There is now no means of making up the subject of materia medica from the British Pharmacopœia until the student labours for weeks and makes out the various lists for himself after much toil and loss of time. This innovation, we fear, will prevent the work making any headway to popularity notwithstanding its manifold improvements. If the committee could have seen their way to put the preparations of each drug under the heading of the drug as is done, for example, in Squire's "Companion to the British Pharmacopœia" the work would have been of enormous value to practitioners and students. As it is we fear it must remain till next revision a volume almost entirely patronised by pharmacists. There is no reason why the reader should have to turn to about twenty-five different places to look for the different preparations of opium—these might all be given upon succeeding pages under "Opium." The busy practitioner does not see why all the tinctures must be printed together; in prescribing he needs a bird's eye view of all the preparations of each drug and their constituents. Notwithstanding this difficulty in the matter of rapid reference we take the opportunity of urging every medical man to have his Pharmacopœia at his elbow in his consulting-room and we would advise teachers of materia medica to recommend their students to use the work in following lectures and especially in studying the physical characters of the specimens of roots, barks, crystals, &c. In no other work are these so carefully and accurately defined.

Fortunately for the practitioner there is no change in the system of weights and measures: he may rejoice that a long respite is given him before the metric system will come into force in prescriptions. In the new work the metric system has been introduced wherever possible, and in some cases to be pointed out later the prescriber must be put on his guard about some difficulty arising from its introduction as influencing the strength of preparations. The weights which have been sanctioned in 1864 are still official and it remains one of the strangest of phenomena that few practitioners of medicine have a clear idea of the weights used by the chemist in compounding or dispensing their prescriptions. There is still no official weight between 1 gr. and 1 oz. (which contains 437·5 grains). When the physician writes a recipe containing the symbol ℈ the British Pharmacopœia still directs that 20 gr. should be dispensed, and if the symbol ʒ be employed in a recipe it is still to be taken as meaning 60 gr. if it stands after a solid substance. If the reader wishes to realise the condition in which this subject of weights is at present we would suggest to him a simple experiment. Let him ask the first half-a-dozen Licentiates of the Pharmaceutical Society whom he meets what number of grains they would weigh out for a saline substance in a prescription ordered by the symbol ℥. Substances like sulphate of magnesia, chlorate of potassium, chloral hydrate, iodide of potassium, &c., are prescribed many thousands of times every week in England in this way and very often the physician (if he has any *definite* idea of the number of grains which his patient should get in his mixture) is labouring under a misapprehension and sometimes the chemist is hazy about the matter. The British Pharmacopœia still recognises no symbol for fluid measures under one pint except the English contractions—min., fl. drm., fl. oz. Many chemists have never seen a recipe containing these symbols or contractions. It is more than ever desirable, therefore, in prescribing solids to discard the old troy symbols and to order always the amounts or weights in grains according to the avoirdupois system, which begins with the troy grain and ends in the avoirdupois pound of 7000 gr., the only intermediate weight being the ounce of 437·5 gr., written oz.

Next to weights and measures comes the important subject of dosage. The practitioner will find that the doses in the new volume differ materially from those in the 1885 Pharmacopœia. When referring to important preparations we shall draw attention to the alteration of dosage, but here it will suffice to point out the general nature of the changes made: 1. The doses of the new British Pharmacopœia will be found to be much more *uniform*. 2. They are much less *inconsistent* than before. Thus, if we take the different preparations of a drug it will be found that the dose has now been calculated upon the basis of the strength of the preparation. Formerly it was not unusual to find that the dose of a crude drug was only a fraction of the dose of the same drug in some of its preparations. This inconsistency was very noticeable in the digitalis and ergot preparations. 3. The doses are, as a rule, much smaller, the intention being to give average doses; but in some instances this has been carried too far; the drug in the smaller dose prescribed is uncertain or inert—for example, the dose of Rochelle salt is given as from 120 to 240 gr. and of antifebrin as from 1 to 3 gr. 4. A distinct departure has been made in many instances in giving two sets of doses, one for a single administration and one for repeated administration as in the magnesia and many other preparations. 5. Lastly, an honest attempt has been made to bring the doses of the various groups of preparations into a more satisfactory condition; for this the practitioner should be profoundly thankful. In the 67 tinctures, for example, the dose is either from 5 to 15 mins. or from 30 to 60 mins., with the one solitary exception of the case of tincture of iodine. This exception could easily have been removed by calling the tincture of this substance a weak liquor and removing it entirely to another group. It is not a tincture in the ordinary sense of the term. In the group of extracts the practitioner will find great assistance in the new dosage.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The forty-ninth annual meeting of the governors and subscribers of the above hospital was held in the Bell Medical and Surgical Library on Tuesday, March 8th. The number of in-patients treated during the past year has been 2047 and the number of out-patients 13,382. The income has been £9253 14*s*.

THE LANCET.

LONDON: SATURDAY, APRIL 23, 1898.

IT is impossible to deny that the action of the General Medical Council in November last in formulating a Notice to registered medical practitioners in advance, as respects clearness and stringency, of previous notices of the sort has been generally regarded by the profession and the public with satisfaction. Even unqualified assistants themselves have not ventured to question the abstract justice and reasonableness of such action on the part of the Council. No doubt to many men of this class it has come as a severe if somewhat belated reminder that they were in a false and unsatisfactory position. The Council for many years connived almost completely at the use of unqualified assistants until reminded by the Home Secretary of the day that it was responsible for scandals which arose out of their employment and that it had the power to deal in a disciplinary way with registered practitioners whose countenance alone kept the class of unqualified assistants in existence. For many years more, down indeed to the present time, the Council has acted with remarkable leniency and toleration towards the class of unqualified assistants and has virtually only punished the practitioner for using such in very gross cases—for the most part in cases of covering, where the unqualified assistant was left practically in complete charge of patients or in the management of a branch practice with little or no supervision by his principal. It is notorious that until very lately it was not uncommon for several large separate practices under the name of one registered practitioner to be practically conducted by unqualified assistants. The fact is that the sense of hardship produced by the recent action of the Council has been occasioned mainly by its past slackness in regard to this great evil, so that unqualified assistants came to think themselves an indispensable and almost a recognised class. The slackness of the General Medical Council in this matter was injurious alike to the public and the profession and it has been cruel in its operation on the unqualified assistants, who have come to regard themselves almost as having rights and claims similar to those which practitioners before the year 1815 had when the Apothecaries Act came into force. This view is quite untenable. The Medical Acts would be stultified if under the thin cover of supervision by a registered practitioner unqualified assistants were to be foisted on the public. The public would be defrauded and very great injustice would be done to young practitioners who attain a place in the Medical Register by years of hard study and after undergoing the ordeal of many examinations. Accordingly, the action of the Council has been generally approved and will, doubtless, be steadily maintained.

Our readers will have seen[1] that a movement is on foot in favour of a strictly limited section of the class of unqualified assistants. It is proposed to petition the General Medical Council to authorise the examining bodies, or certain of them, to hold, if they please, one or more special examinations, during the present year alone, for the benefit of such unqualified assistants as, firstly, are over forty years of age, secondly, have completed the medical curriculum, and, thirdly, are of satisfactory moral character. It is essential that in sanctioning any such accommodation to unqualified assistants the Council should stipulate for conditions which imply that the non-qualification of men has arisen rather from their misfortune than from their fault. It is easily conceivable that there are not a few men who have been hindered by little fault of their own from obtaining diplomas which would have entitled them to registration. Want of health, want of means, failure of parental help at an inconvenient stage of their career, and such like things, are only too common and happen often to students of good character and of good ability. It cannot be to the interest of the profession to throw these men adrift into the ranks of illegitimate practice and if any reasonable plan can be adopted for legalising their position few will object to its adoption. It is significant of the impression that such a step would be consistent with justice that it is approved and promoted by registered medical men. It is not asked that such an exceptional gate of entrance to the profession should be kept open for more than the present year. It would be no kindness to the class whose legalisation is contemplated to keep it open for any length of time. They must clearly realise that the profession is to be closed quickly and completely to all who have not complied with the requirements of the examining bodies and the General Medical Council. But it does seem to us that the petition in favour of this limited class of unqualified assistants may be seriously entertained by the Council without detriment to the public or the profession.

[1] THE LANCET, April 9th, 1898, p. 1013.

WE remember holding a conversation some years ago with a distinguished American in which allusion was made to the want of friendly feeling exhibited by the newspaper press of the United States towards this country, the reason of which was inexplicable to us. The feeling of England to the United States, we urged, has always seemed to be most friendly; the official representatives of that country were very popular in London society, and Americans were everywhere received in England on terms of the frankest friendship. Our American friend in effect replied: "Never mind these surface exhibitions of apparent hostility, for they are but apparent, not real. If your people were in a great strait and were making a hard fight—which you would—against any big coalition against you there would be no holding my people; there would be such a flood of feeling in your favour as would sweep everything before it." We believed that at the time and we believe it now. There is, and always has been, an underlying conviction on this side of the Atlantic that, in spite of all our differences and diversities and methods of procedure, the Anglo-American race is one; that in our love of a just and law-abiding rule, in our love of freedom, independence, and progress we recognise and are

working up to the same standards; and that, in fact, blood is thicker than water.

As we have so often said we have happily nothing whatever to do as medical and scientific journalists with politics, but it is difficult to prevent a subject that meets the eye in every newspaper at the present moment from obtruding itself into our thoughts and influencing our sentiments. It is also impossible for people in this country not to feel some sorrow and sympathy with Spain, with all her historical traditions and past power, placed as she now is in the most difficult and trying situation possible. But looking to the future good of humanity, and believing, as we do, that the sincerest and best people, at any rate, in the United States, are moved by a spirit of unselfish indignation at the protracted misrule of Spain in Cuba, we cannot withhold our sympathy with them and the cause they are championing, or avoid perceiving that it is for the good of the world that such cruel misrule should be brought to an end. If Spain had long ago spontaneously adopted the course she is now prepared to accept the case would have been different, but her concessions come too late. Our contemporary, the *Spectator*, correctly hit off the situation, we think, when it said that Spain has some supporters in this country because she is thought to be so weak and the States so strong. "The real test of public opinion, however, is the admitted fact that the Government, even if they wanted to, which they certainly do not, could not show the slightest hostility to the States without creating an opposition so strong that it would bring them to ruin." What precipitated matters, no doubt, was the *Maine* disaster and the belief in the United States that its cause was not purely accidental but attributable to the culpability or negligence of the Spaniards—a view which has not been proved and which the Spanish Government scornfully repudiates. It is, we think, easy to trace one of the causes of the somewhat tentative and contradictory lines of policy put forward in the United States. They have never relinquished the object in view—namely, the complete evacuation of the island of Cuba by Spain, but the hope has nevertheless been entertained that this object might be somehow attained without war. Mr. MCKINLEY has made that much apparent. While it was very important to guard against the idea that it was only a case of NABOTH'S vineyard—a case of land-grabbing—it was also necessary to protect the United States Government against being entangled in the meshes of a doubtful Cuban Republic constituted by insurgents.

From 1823 to the present time the history of Cuba has been one of chronic discontent and periodical insurrection against Spanish rule, and it was, we repeat, inevitable that the United States would intervene to put an end to the terrible state of things there if the Spanish Government could not pacify its Cuban subjects. It is scarcely likely that Spain under existing circumstances could now submit to give up Cuba altogether and withdraw her forces from the island (by which alone war could have been averted), for such a course would probably give rise to a revolution and endanger the present dynasty, but she may be glad to do so under cover of a defeat. We can only hope, so long as the final step remains to be taken and war between the United States and Spain has not been actually declared, that it may yet be averted, but the bare hope is all that remains. All the indications, it must be confessed, point in one direction only—that of war; and we suspect that it will prove a very grave undertaking for even so powerful, but unprepared, a nation as the United States. Military and naval experts are already busying themselves with conjectures about its probable course and results. It is quite possible that some decisive naval action may take place at its commencement, but if the result of it were even adverse to the States it could not end the war. Be all this as it may, however, there is a medical aspect of the question which may turn out to be a most important factor. All past experience testifies and everybody knows how much depends upon the season at which war is waged in hot countries. Cuba has the reputation of being a hot, unhealthy, malarious island, where yellow fever may be said to be endemic and occasionally to prevail with epidemic violence. The unhealthy season is notoriously the hot and rainy one, and the healthy is that of the colder months of the year. The losses from fever and dysentery, from the time of ALBEMARLE'S naval expedition in 1762 to that of the large Spanish expedition against the Cuban insurgents of quite recent times, have been excessive. We all know that the death-rate among the large Spanish force was great, although we do not know statistically how great it was; but it was as nothing compared with the total inefficiency caused by sickness, or with the number of sick soldiers in the military hospitals in the island during the hot and rainy season and the large amount of invaliding which followed. We do not, of course, know what is the size of the military force which the United States contemplate landing in Cuba, but there is already a large Spanish army present in the island, and any expeditionary force sent from America, or army of occupation required for holding Cuba until peace and good government have become established, will presumably have to be large. There is no doubt that the United States Government will take all possible care of its soldiers as far as sanitary precautions and the provision of excellent hospitals are concerned, but we fear that the sickness and loss of life will in any case be large and that it may, on the outbreak, and in the presence of any epidemic disease, be excessive.

THE March issue of the *Sanitary Journal*, contains a characteristic article by Dr. J. B. RUSSELL, entitled "Public Health and Social Problems." It appears to have been delivered as an address to a students' society in Glasgow University, and though we fully recognise the ability of undergraduates to appreciate a good thing, it almost seems that the lecturer might have found at least a larger and a wider, if not a more appreciative, audience. But when we recollect that that gem of public health literature, the address on "Life in one Room," was originally given to some local mutual improvement society, we begin to see that the question of an audience is a secondary one with Dr. RUSSELL, even when he has something very particular to say. Briefly, the thesis of the present paper is that sanitation is doing a great deal to remove the chief causes of discontent on which modern socialism is founded, that it is capable

of doing still more, and that it is at least a more practical if not essentially a better remedy. "The difference," says Dr. RUSSELL, "between all those social architects and the sanitarian is this: the sanitarian is like the lifeboat or the lifebelt to the drowning man—'a very present help'; the theorist is like the lecturer on the art of swimming—any good he may do is in the future. He certainly will not help the drowning man." As to the causes of increased population in certain parts of the country we read that "Glamorganshire presents the most remarkable illustration in the country of a purely rural county, slumbering, so to speak, over untold wealth, entirely unconscious of its existence, and transformed by its discovery into a sweltering land of coal-mines, ironworks, copper- tin- and lead-smelting works, its shores lined with docks and bristling with the masts of ships. Such is the wondrous tale, excelling all the marvels of Aladdin's lamp, which is hidden in the dry bones of this bit of statistics, that between 1801 and 1891 the population of Glamorganshire increased 835 per cent." Having shown how largely the population of Great Britain has migrated from the country to the town Dr. RUSSELL points out what this migration means socially and politically as well as sanitarily:—

"As I look at these percentages creeping up from decade to decade they become not merely sanitarily but socially and politically eloquent. They mark the emancipation of the people from obscurity.

> Not kings and lords, but nations,
> Not thrones and crowns, but men.

It is difficult for an agricultural population to realise its strength. But in cities the numerical superiority of those who are employed over those who employ cannot be hid and must suggest thoughts. Physical aggregation promotes moral association. Following Watt's discovery there comes a period of English history which the historian demarcates as 'The Conflict with Democracy, 1789-1827.' We are not here and now concerned with politics, but multitudes have a profound, even a pathetic, interest to the sanitarian, and as I consider them from my point of view I cannot shut my eyes to their fortunes and misfortunes, their virtues and their vices. I see them wakened up by the Revolution in France, then becoming definitely visible through the 'hurricane eclipse' of the Napoleonic wars; fighting for their country as vigorously in the factory and workshop, with the help of steam, as their brothers under arms in the Peninsula or afloat with Nelson; starving when the peace they had helped to win left the Continent free to compete with them in the arts of peace; in the blindness of despair, burning mills, clamouring for the suffrage, rioting, ridden down by the cavalry at Peterloo; gradually gaining the protection of the Factory Acts and emancipation from the new slavery of the apprenticeship system, secured from starvation by the abolition of the Corn Laws and the adoption of free trade; finally, struggling through Chartist riots towards political enfranchisement and the Ballot Act. There, masters of their own destinies, we may leave the Democracy."

Another fine passage begins as follows:—

"What is the fulness of the meaning of a lowered death-rate? How can I bring it home to you? Marshal all the physical facts which constitute the scientific conception of summer and winter, and how much nearer are you to knowing what they are? A few hours more or less of sunlight, a few degrees more or less of heat, a few inches more or less of rain; a mile or two of velocity, a pound or two of pressure more or less of the wind, and a point of change in the direction from which it comes, that is all the difference, and yet summer is life and laughter, winter is death and tears. It is much the same with the statistical expression of the movements of public health—a unit or two or only a decimal fraction of a unit more or less, that is all, whether we adhere to the simplicity of a death-rate or resort to the intricacies of a life-table."

Space prevents us from quoting further, but we trust that Dr. RUSSELL or the publishers of the *Sanitary Journal*[1] will be so inundated with requests for copies that it will be necessary to reprint the lecture for general circulation. It should have been given as the opening address of a Social Science Congress or from the presidential chair of the British Association for the Advancement of Science.

Annotations.

"Ne quid nimis."

THE CONTROL OF PUBLIC WATER-SUPPLIES.

Is it not time that the quality of public water-supplies throughout the country should be placed under the same legislative control and check which obtain at the present time in regard to food and drugs? A short yet very comprehensive Act involving but little need of additional organisation would appear to be all that is required. Big supplies like the metropolitan supply are, as is well known, periodically and minutely examined, but the public water-supply of the majority of provincial towns is not as a rule subject to the same officially conducted examinations. Yet if such a scheme were established throughout the country we should undoubtedly possess in it a power to prevent as far as is humanly possible the occurrence of epidemics of water-borne disease. Is not this the lesson which we ought seriously to take to heart from the great epidemics at Maidstone, Lynn, and elsewhere. The purity of a water-supply is one of the most vital matters concerned with the health of the community and, oddly enough, the community in this matter has but feeble protection afforded to it by its own specific laws. How far under the present *régime* protection is secured may be gathered from the utterly incongruous state of affairs which is brought to view when cases of dispute as to the purity of certain supplies come before public notice. First and foremost there is the totally erroneous idea frequently harboured by town councillors and others in authority that Somerset House is the tribunal in such cases. It is true that the Somerset House laboratory is for the present the place of reference for disputed samples taken under the provisions of the Food and Drugs Act, but the officials at Somerset House are widely deviating from their proper sphere and function when they take upon themselves to give a final decision as to the fitness or unfitness of a given source of water-supply. And if these officers go upon the lines which they have evidently adopted in recent cases they may produce endless mischief and undo much of the excellent work undertaken at great pains by our sanitary officers. To take one example. In THE LANCET of March 26th we referred to the extraordinary opinions expressed by the members of a certain town council as to the action of their surveyor who, when submitting a sample of water to the analyst, afforded him certain information upon the source of the water and upon the probability of contamination. The majority

[1] Wm. Hodge and Co., Glasgow.

joined in reprimanding the surveyor for furnishing the analyst with particulars concerning the source. One remarked that "the analyst ought not to know where the water came from" and another that "it was a most outrageous thing that the water should be sent for analysis as this was." "Surely the analyst could find out impurities without leading strings." "Germs might have existed only in imagination in these circumstances." An appeal was made to Somerset House, as is usually done in view of the widely prevailing but ignorant idea, first, that Somerset House is the proper tribunal and secondly, that a chemical analysis alone is sufficient to enable a sound opinion to be given as to the suitability of a water for drinking purposes. We then said that "it is certainly to be hoped that neither the analysts at Somerset House nor any other analyst will venture to express an opinion upon the safety of a water without knowing something of the source from which it is derived." Now, in matters of this kind the Somerset House chemists have frequently posed as referees and their dictum has been accepted by justices, while no inquiry was undertaken by them with that detail which is absolutely necessary into the source and environment of the water. To speak plainly, the chemists at Somerset House have no business to give a pronouncement on these questions at all. The consideration of water-supply is altogether outside their duties and the sooner the public and our justiciary learn this the better for the community. Such incidents make it more urgent that the Government should soon appoint and recognise a court of decision connected with the Local Government Board or a newly-constituted board of health, whose duty it shall be to undertake cases of reference of this sort and inquire practically into cases of dispute with the view of a settlement which shall be satisfactory and reassuring to the community at large.

THE NEED FOR REVACCINATION.

In the singularly able "memorandum" on the Government Vaccination Bill which Dr. Bond has prepared for the Jenner Society, and which, we trust, will be widely circulated, there are some remarks upon the necessity for instructing the public upon vaccination which we heartily endorse. The case for revaccination, too, is so well put that we may quote it in full.

"The experience of every epidemic, and last but not least of that at Middlesbrough, shows conclusively that if we wish to protect the community against these increasingly frequent scourges we must take as much trouble to promote revaccination as we have hitherto taken to promote infant vaccination. So long as the public are led to believe, as they have been hitherto, that vaccination in infancy is the only thing about which the State need take any care, so long will epidemics of so-called 'vaccinated' adolescents and adults and of unvaccinated or badly-vaccinated children be the opprobrium of our country. There is only one way of effecting this, and that is by requiring, so far as is practicable, every child who enters a school to be efficiently vaccinated, and that before it leaves school it shall be equally efficiently revaccinated. It is to the revaccination of her adolescent population that Germany owes the remarkable immunity from epidemics of small-pox which she has for the last twenty years enjoyed rather than to her compulsory vaccination in early childhood. For it is the adolescents and adults whose early protection in infancy has become attenuated by age who are most exposed to the risks of small-pox. If we could secure their protection by revaccination at the end of the school age, as well as that of the children at the commencement of it, we need not trouble ourselves much about the infants. We have been misled in this respect by false inferences from the experience of Jenner and the early vaccinators. When infants were the chief sufferers, because the adult population was in a large degree protected by having had the disease, the discovery of a means by which these unfortunate little victims could be almost absolutely protected naturally led to an undue estimate of the value of infant vaccination, especially as its effects were assumed to be more lasting than they really are. But we have now to deal with altogether changed conditions. Where infant vaccination is fairly well maintained, as it has been in Middlesbrough, it is the adults who have not been revaccinated who are now the chief source of danger—a danger which can only be avoided by investing every young person with the same degree of protection which we have for the last half century conferred upon the greater portion of our infant population."

THE UNIVERSITY OF LONDON.

We regret to find that the Government has decided to postpone the consideration of the London University Bill until the Committee stage of the Irish Local Government Bill—which will begin on Tuesday next—has been disposed of. As the Irish Local Government Bill is the principal measure of the session this means a long postponement, probably until after the Senatorial election, which is fixed for May 16th. The death of Sir Richard Quain has created a vacancy on the Senate which Convocation will fill, according to precedent, by a graduate in arts or law. Two candidates—Mr. James Bourne Benson, LL.D., B.A., and Mr. Fletcher Moulton, B.A.—have issued their addresses and the election will turn solely on the London University Bill, which Dr. Benson supports and Mr. Moulton opposes. The reconstitution of the University on a dual basis for external or non-collegiate students and internal or collegiate students is the only alternative to two universities—one teaching and examining and the other examining only. It is impossible for the present condition to continue, for the metropolis must have a local teaching university. As is well put in a circular signed by the representatives of the London teaching institutions of university rank who waited on the metropolitan Members of Parliament on March 28th, "teaching educates; examinations do not educate; degrees do not educate; they are of value only as tests and certificates of an education which the University teaching alone imparts." We trust that the Government will see that with the Bill as now submitted to the House of Commons stands or falls the whole feasibility of reconstituting the existing University as a teaching university for London. It would be a severe blow to the reform of higher education in London if the labours of the last twelve years were to be rendered fruitless.

QUACKS AND QUACKERY

In a Brisbane newspaper, dated Feb. 26th, is a presumably editorial article headed "Quacks and Quackery." With most of the sentiments therein expressed we are in cordial agreement, though they are set forth embellished with flowers of rhetoric to which we in this less romantic land are but little accustomed. "If we abhor," says the writer, "the respectable commercial swindler, we absolutely loathe the quack. The quack is in the lowest layer of the human dunghill. ..... Wherever one sees the glitter of brag one is justified in suspecting the absence of *bona fides* and should search, so to speak, for the horns, hoofs, and tail of the advertiser. When added to the glitter aforesaid there is also accompanying evidence that the alleged curer is merely a bird of passage, roosting like a buzzard in our midst until he shall have secured a bellyful of garbage, one may take the horns, hoofs and tail for granted." The article goes on to ask whether it would not be possible to penalise persons not duly qualified from pursuing the occupation of real or pretended curing of diseases. "This would not affect genuine patent medicine inventors ..... for the restrictions and conditions surrounding the granting of a patent are in themselves some sort of guarantee

that the public health is safeguarded. Further, could not all self-advertising dealers ..... 'pill' vendors, &c., be compelled to take out licences?" Now, would anybody believe that on the very same page with this impassioned article is a half-column advertisement of the well-known type, containing the well-known lies, of Dr. Williams's Pink Pills? As Mr. Yellowplush remarks, "I coodn't suppose anythink mussenary in a littery man," so perhaps the editor of the paper in question would do well to revise his advertisement columns.

THE AUTUMN CONGRESS OF THE SANITARY INSTITUTE.

As we have already been able to announce, the autumn congress of the institute will be held this year in Birmingham, under the Presidency of Sir Joseph Fayrer, commencing on Sept. 27th. The Council hope that all the members will endeavour to be present and that many will contribute papers so as to make the congress of the institute thoroughly successful. We are asked to announce that the programme, showing the arrangements already made, will appear in the journal of the institute. All further information concerning the programme, the reading of papers, &c., can be obtained from Mr. E. White Wallis, the secretary, by applying to him at 72, Margaret-street, W.

THE BETTER CONTROL OF ANTHRAX.

A RECENT communication on the subject of anthrax, which was addressed to the *Times* by Sir Herewald Wake, raises the question whether it is not practicable to exercise a more thorough control over this disease than is at present the case. Sir Herewald Wake refers to an outbreak which apparently occurred last autumn on a farm on his own estate in Northamptonshire by which six head of livestock were affected and by which probably a young woman on the farm lost her life; two men seem also to have been attacked but both recovered. The main point, however, upon which the writer of the letter insists is that this outbreak was caused by a previous but unreported outbreak of the disease on the same farm, and the omission of the occupier to report this first outbreak, and the system which allows of such omission, are severely condemned. Unfortunately anthrax is not alone liable to these sins of omission and to a large extent the same objections can be raised against our whole system of notification as carried out under the Notification Act. Unless, for instance, we can bring home to a parent, or other person responsible for notification, the fact that a case of infectious disease notifiable under the Act has been intentionally concealed we can obtain no redress. Can this defect in the case of animals suffering from anthrax be remedied? Sir Herewald Wake thinks that an improvement would be effected if, in order to bring to light doubtful cases it were enacted that if such a case turned out on examination to be anthrax, moderate compensation, which he suggests should be one-third of the value of the first animal attacked, should be paid. This certainly seems to be a reasonable suggestion and one for which something is to be said: it is not open to the objection which a proposal to pay a certain fee for the notification of all doubtful cases would be. Obviously every encouragement should be given towards ascertaining the early existence of anthrax, as the amount of mischief which might conceivably be done by an unrecognised case from the specific pollution of a grazing meadow is considerable. It does, too, seem to us to be a most important point that proper precautions as regards disinfection, &c., should be taken in outbreaks such as that under consideration, in which the circumstantial evidence points to the existence of certain previous cases. It is perfectly true that in some instances the bacilli of anthrax are after a few days destroyed by putrefactive organisms, so that absolute proof of a pre-existing case cannot be obtained; but this fact should not in our opinion justify the omission of proper precautions to prevent the inferentially invaded locality from continuing to act as a source of danger. Precautions such as we suggest would certainly be taken by a medical officer of health when dealing with a probable source of infection.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT.

WE print on page 1137 a memorandum which was issued from the Home Office during the week dealing with these new and important appointments. We are glad to recognise that the scale of fees approved by the Treasury is a liberal one. Applications for the appointments should be addressed to the Home Secretary (*vide* p. 1138).

EARLY PREGNANCY.

DR. SAGE of Bordeaux recently delivered by means of forceps a girl, aged thirteen years and six months, of a male child at term weighing 8½ lb. The mother seems to have become pregnant a month after her first menstrual period. There was nothing abnormal regarding the puerperium. This has led Dr. Sage to look up the subject of early pregnancies, which are less common in France than in other European countries. He has been unable to find any mention of a case occurring at so early an age as his own in recent medical literature, the earliest being at the age of fourteen years and one month. In a medical dictionary published in 1823 mention is made of girls having been received into the Paris lying-in hospitals at thirteen years of age, and during the Revolution at eleven years and even before that age. The earliest cases recorded in other countries are Molitor's case in Luxemburg, where a child, aged eight years and three months, became pregnant and was delivered of a mole containing a dead fœtus seven months afterwards (this was in 1877); Outrepont's case (1825) of a German girl, aged nine years, who aborted in her fourth month; Haller's case in Switzerland of a girl born in 1751 and delivered in 1759; and Dodd's case in England (1881) where a Yorkshire girl, aged nine years and eight months, was delivered of a living child at term. Here the young mother had menstruated from twelve months of age. In Neale's Digest a reference is given to another case at eight years.[1]

BILATERAL HOMONYMOUS HEMIANOPIA.

DR. KARL KÄSTERMANN of Hamburg has recently contributed to the *Monatsschrift für Psychiatrie und Neurologie* a very interesting paper on this subject, of which an abstract appears in the *Neurologisches Centralblatt*. He relates the history of two cases of double-sided homonymous hemianopia in one of which a careful microscopical examination was made. He has collected 27 cases from the literature of the subject and he finds that as a rule the optic discs in such cases were normal, that the acuity of vision was rarely impaired, that the pupils usually react normally and that the action of the external ocular muscles is not interfered with. Colour-sense was, as a rule, retained, but usually there was interference with the memory for places and with the patient's power of localising himself. Mind-blindness and hemiplegic weakness both occurred. Some patients were rendered totally blind, but as a rule the fixation point, with a more or less extensive peripheral area, was retained. The peculiarity of one of Dr. Kästermann's own cases was the loss of the whole of the field with the exception of a peripheral homonymous

[1] See Medical Times, vol. i., 1878, p. 276.

zone of the left field. In this case there was at first homonymous hemianopia and subsequently an attack of left homonymous hemianopia producing blindness. With this second attack there was disturbance of the patient's recollection for places and also symptoms of mind-blindness. At the necropsy areas of softening were found in both occipital lobes. In the region of each calcarine fissure there was an area at the floor of the fissure which had escaped. Dr. Kästermann from his researches concludes that the area subserving the visual fields is the cortex in and around the calcarine fissure and that disturbances of recollections of places, &c., depend upon lesions of the posterior lobes. In all cases in which there was permanent disturbance of place recollection there were found lesions in both occipital lobes.

AN UNFOUNDED CHARGE.

ONE of those unpleasant incidents which are only too common in the life of a medical man was the subject of inquiry before a Birmingham police-court when Mr. L. V. Parry, a surgeon of Asylum-road, was brought up charged with committing a criminal assault upon a woman named Matthews. The prosecuting solicitor said that since the case had been put into his hands he had examined the witnesses for the prosecution and was of opinion that the evidence did not support the charge. The prosecutrix had been treated for hysteria, the evidence of two important witnesses disagreed, and he asked the Bench to withdraw the case. The magistrate said: "The case is withdrawn and the defendant is discharged. Such cases frequently occur. It is one of the dangers of medical life and the court feels much sympathy with any gentleman subjected to such a charge as this. No doubt the lady believes what she says. Mr. Parry, you are entirely and completely exonerated." Mr. Parry has our sincere sympathy in having been exposed to such an ordeal. Such a charge is very easy to bring and not always easy to refute and the mere appearing in answer to such a charge is most disagreeable, to say nothing of the expense and waste of time which is involved in addition.

VITAL AND VACCINATION STATISTICS IN SCOTLAND.

THE Scottish Registrar-General's Report on births, deaths, and marriages in 1897 and vaccination in 1896 has now been issued. The birth-rate was 30·5 per 1000, the death-rate 18 7, and the marriage-rate 7·3. For registration purposes Scotland is divided into principal town districts, containing towns with over 25,000 inhabitants; large town districts, containing towns with between 10,000 and 25,000; small town districts, containing towns with between 2000 and 10,000; and mainland rural and insular rural districts. The birth-rate in the principal town districts was 31·9, in the large town districts 32 4, in the small town districts 31·1, in the mainland rural districts 27 4, and in the insular rural districts 21 4. The illegitimate births were 6·98 per cent. of the total, the rate in the various counties ranging from 3 8 in Shetland and 4·1 in Ross and Cromarty to 13·5 in Caithness (which geographically is midway between Shetland and Ross and Cromarty), 13·5 in Elgin, and 14 1 in Wigton. The divisions with the highest rate of illegitimacy are the North-eastern, 11·8, and the Southern, 11·7. The total rate of 6·98 per cent. for the whole country is the lowest since the coming into operation of the Registration Act in 1855. The highest rate was 10·2 in 1866 and since that time there has been a very steady though very gradual decline. The death-rates per 1000 were 20·8 in the principal town districts, 18·7 in the large town districts, 17·7 in the small town districts, 16·3 in the insular rural districts, and 16 2 in the mainland rural districts. The vaccination statistics for 1896 show that of 129,245 births 110,033 were successfully vaccinated, 12,181 died before vaccination, in 2843 the vaccination was postponed, 544 were found constitutionally insusceptible, 286 were insusceptible owing to previous vaccination, and 3358 had removed from the district before vaccination or were otherwise unaccounted for. The percentage of cases unaccounted for was 2·598, or reducing the total by deduction of the deaths before vaccination 2 868. These percentages are a little higher than the average of the previous ten years, which were 2·404 and 2·653 respectively. There has, however, been very little variation in the decade. The lowest default (omitting the deaths before vaccination) was 2·365 in 1894 and the highest 2 897 in 1889. Some extracts are given from local registrars' notes which help to explain even the small existing default. At Lochbroom an epidemic of measles was responsible; at Waternisch there was delay not in vaccination but in certification; in North Harris the severity of the weather had caused the vaccinator to postpone his work till spring; and at Lasswade and Liberton many families had removed owing to the closing of oil works. Even in Scotland, however, there seems a slight tendency to the spread of the anti-vaccination craze and one or two recent imprisonments, with their consequent *éclat*, may have the same evil effects as have sometimes followed such occurrences in England. Would it not be advisable that the Scottish Vaccination Act should be amended by abolishing repeated penalties?

THE MICROSCOPE AND THE EARLY STAGES OF CANCER.

THAT microscopic examination is a valuable aid in the diagnosis of cancer and in doubtful cases a decisive test is generally held. Such is not the view of Mr. Hutchinson. In a recent number of his *Archives of Surgery* he insists that the microscope can give no aid in the recognition of the precancerous stages of cancer. For a long time he has been a warm advocate of early operations and in certain cases of their performance before absolute certainty in diagnosis can be felt. He states that in well-pronounced conditions microscopic examination is not needed and in doubtful ones it cannot assist. Characteristic appearances in the mode of growth and the manner of ulceration are almost always obvious to the instructed eye before the histological conditions have become such that they can be trusted. Thus, according to Mr. Hutchinson, in their early stages cancerous growths are not histologically cancer; chronic inflammatory changes almost invariably precede for a longer or shorter period those which are definitely malignant. A negative result with the microscope often begets a false security and leads to a loss of time which it is impossible to retrieve. Mr. Hutchinson finds that this is constantly occurring; in the previous month he saw four such cases. A man had a large and most characteristic epithelial cancer in his soft palate in a stage almost too late for excision. Eighteen months previously a portion had been cut away which on microscopical examination was pronounced not to be cancer. Mr. Hutchinson asks, Would it not have been better to have removed the whole? In a case of ulcer of the tongue the patient was assured as the result of microscopical examination that he was not suffering from cancer, but two months later the contrary was proved. On one occasion Mr. Hutchinson removed the whole tongue for what he believed to be a broken-down cancerous mass which had suppurated. An experienced pathologist who examined the specimen assured him that there was no cancer but simply an abscess cavity. Within a few months, however, the glands enlarged and in less than a year the patient died. In a case of cancer in the palm of the hand occurring after prolonged administration of arsenic, microscopic sections were made which were

examined by various authorities in America, in this country, and on the Continent, with the result that most diverse opinions were given. Several insisted that the disease was syphilis and not cancer. Mr. Hutchinson asserts also that the discrimination between syphilitic changes and inflammatory hypertrophy is also beyond the powers of the microscope; there may be features which may guide the judgment but they are often fallacious and he who trusts to them will make blunders.

WHY INQUESTS ARE HELD.

ACCORDING to the *Manchester Evening Chronicle* Mr. Sidney Smelt has been explaining to a coroner's jury at Manchester for what purpose inquests are held. He said that they were not scientific inquiries into the cause of death, though many people thought that such was the case, and unfortunately the idea had been fostered by medical men. Whether they wanted to obtain scientific knowledge from such inquiries or whether they desired to get fees for giving evidence was best known to themselves. In no sense was a coroner's inquiry a medical inquiry and medical men had nothing to do with it except to give evidence when called upon. Inquests were held to find out whether anybody was to blame for death, and he was sure the public, for whose protection they had been established, would strongly oppose the holding of them for scientific purposes. If they were to have scientific inquiries they must have them in every case of death. It was not right that medical men should force themselves upon a jury merely because death had been sudden. Such was not the intention of the Legislature. Nobody ever imagined that a coroner's inquest was a scientific inquiry; but as Mr. Smelt allows that their object is to find out whether anybody is to blame for the death, how is this desirable result to be arrived at without medical evidence as to the cause of death? Supposing the body of a person is found in a stream or a pond, who is to say whether he or she was alive or dead when he or she got in to the water except a medical man? Of course if a man is cut to pieces by a train or a tramcar there is no need of medical evidence, but there is great need in cases of bodies found dead or in the case of persons who have died without proper qualified medical attendance. We should be glad to know, too, what Mr. Smelt means by implying that medical men force themselves upon a jury? It is the duty of the coroner to summon medical evidence if he thinks proper.

CEREBRAL HÆMORRHAGE IN EARLY LIFE.

FROM time to time cases have been published by competent observers of cerebral hæmorrhage in early life on which the necropsies threw no light. Neither the organs nor the vascular system showed any signs of disease. Here is an unsolved pathological problem. In the *West London Medical Journal* Mr. Maitland Thompson has recorded the following case. A strong and healthy boy, aged thirteen years, had a mild attack of varicella. At the end of a week he complained of slight headache and photophobia and vomited. He became comatose; the right pupil was widely dilated and the left was contracted. Convulsions set in and he died ten and a half hours after the seizure. The vessels of the dura mater and the pia mater were much congested. The right lateral ventricle was full of blood clot and the brain substance was ploughed up in the neighbourhood of the temporo-sphenoidal lobe, the hæmorrhage having probably come from the lenticular striate branch of the middle cerebral artery. All the organs, the heart, and the arteries were healthy. It seems to us difficult to avoid the conclusion that the varicella was in some way a cause of the hæmorrhage. Trivial as the disease usually is, it is in rare instances attended by serious and fatal complications. In an annotation in THE LANCET of Oct. 9th, 1897, we called attention to varicella gangrenosa which may prove fatal to previously healthy children and for which a microbial origin has been suggested. Similarly a microbial affection of a cerebral artery leading to perforation and hæmorrhage might be invoked in this case and the same explanation might be extended to other cases of this class.

THE STATE CHILDREN'S AID ASSOCIATION.

THE State Children's Aid Association, of which the Right Hon. Lord Herschell is chairman, has just issued its first annual report. The main object of the association is to obtain individual treatment for children under the guardianship of the State, the secondary object being to obtain for the State further powers of control over neglected children. A Bill for the better control of Poor-law children was drafted under the direction of the association and introduced by Mr. Ernest Flower, M.P., into the House of Commons towards the close of the last session. This year it will be again before the House. It is interesting to note that this association has been somewhat instrumental in prevailing upon the Metropolitan Asylums Board to build an Ophthalmic Hospital School at Brentwood in small cottages, each cottage not to contain more than ten children, and the whole institution to be limited to 270 inmates. In tendering his resignation as chairman of the association at the close of the year Lord Peel wrote: "Whether inside or out of Parliament the effect of the association will command the sympathy of all who desire to improve the condition and elevate the character of thousands of children, who have the strongest claims to intelligent and careful treatment." And with this we cordially agree. The report can be obtained, price 3*d*., at the office of the State Children's Aid Association, 61, Old Broad-street, and also at Messrs. King's, King-street, Westminster, S.W.

PHYSIOLOGY OF THE SPINAL CORD IN AMPHIBIA AND REPTILES.

SOME interesting observations on the time occupied in the performance of reflex acts of the spinal cord in animals amongst amphibia and reptiles have recently been made by Herr Adolf Bickel and have been reported in the *Physiologische Archiv* of Pflüger. Herr Bickel was led to undertake his researches from the perusal of those of Rosenthal on the same subject. Rosenthal found that the time was dependent partly on the strength of the stimulus, partly on the part of the periphery to which the stimulus was applied, and partly upon the seat of termination in the nerve centres of the sensory nerve excited. In Herr Bickel's first set of experiments winter frogs were employed, in a second set lizards, and in a third set tortoises. In one series of frogs the cerebrum and cerebellum were removed, leaving only the medulla oblongata and the cord; in another series the medulla oblongata was also removed, so that the animal was left with only the spinal cord; and in a third set the cord was divided between the fourth and fifth vertebræ. In the former set pulmonary respiration was not interfered with, whilst the animals exhibited great motor activity, creeping restlessly about the basin in which they were kept, and in the course of a few days they as usual showed greatly increased reflex excitability of all the limbs. In the second set of frogs, in which the cord had been divided just below the calamus scriptorius, respiration was again not interfered with, but the capability of movement in the anterior limbs was slightly impaired; the hind limbs were usually kept drawn up, but their motor mechanism was not interfered with. In the third set the animals lived and usually, as in the last set, kept the hind

limbs adducted and responded in the most lively manner to stimulation. On testing the time occupied in the performance of reflex acts in these several sets of animals Herr Bickel found that in those frogs in which the cord was divided between the fourth and fifth vertebræ the time elapsing between the commencement of stimulation of the toes and the reflex act of muscular contraction was considerably *greater* than in those in which the cord had been divided at the calamus scriptorius. On the other hand, there was only a small reduction in the time which elapsed between stimulation and motor reaction in animals which possess spinal cord *and* medulla and those which only possess the spinal cord. Expressing the facts in somewhat different language, it may be said that the reaction time, with equal strength of stimulus, identical point of stimulation, and equal amount of reflex contraction, is in the frogs of the first group very little shorter than in the second, whilst in both these groups it is much shorter than in the third group.

THE WESTMINSTER HOSPITAL.

ON May 11th a concert is announced to be given at St. James's Hall in aid of the funds of the Westminster Hospital. The concert differs from the usual run of such events in that it is practically a kind of "three choirs estival," for three societies are going to give their help—namely, the Westminster Orchestral Society, the Reigate Choral Society, and the Streatham Choral Society. An interesting provisional programme has been issued and we may hope that the proceeds of the concert will go far to relieve the committee of the hospital from their pressing financial difficulties. The greatest care will be taken to produce the concert upon the most economical terms so that the hospital may benefit as much as possible. The concert is under the direct patronage of H.R.H. the Princess of Wales and T.R.H. the Duke and Duchess of York. The good work which the Westminster Hospital does is well known and since its establishment in 1719 it has treated one and a half millions of patients. Tickets may be obtained from Mr. Basil Tree's office at St. James's Hall or from Messrs. W. E. Hill and Sons, 140, New Bond-street, and on and after May 1st the price of numbered tickets will be increased from 7*s.* 6*d.* to 10*s.* 6*d.* and from 5*s.* to 7*s.* 6*d.* respectively.

THE LONDON POST-GRADUATE COURSE.

ON Monday, May 2nd, the summer term will commence. There will be classes at the Hospital for Diseases of the Skin, Blackfriars, on Skin Diseases; at the London Throat Hospital, Great Portland-street, on Diseases of the Throat, Nose, and Ear; at King's College on Bacteriology; at the Parkes Museum on Hygiene and Public Health; and at Cleveland-street on General Medicine and Surgery. A course on Mental Diseases will be given at Bethlem Hospital from Aug. 2nd to Aug. 12th. Fees may be paid and entries made on application to Dr. Fletcher Little, secretary, 32, Harley-street, W.

THE VACCINATION BILL AND PUBLIC BODIES.

THE following resolutions were adopted at a conference of delegates representing various societies interested in public health and recently convened by the Incorporated Society of Medical Officers of Health:—

"That evidence of efficient vaccination should be afforded on the admission of a child to a public elementary school.

"That the Vaccination Bill should contain a definition of 'efficient' vaccination.

"That the powers and duties with regard to vaccination should be transferred from the Poor-law to the sanitary authorities.

"That the Government should pay for vaccination performed by general medical practitioners, subject to the vaccination being done in accordance with the regulations of the Local Government Board and being open to inspection.

"That it is essential that the State should take steps to require the revaccination of all persons on their attaining the age of twelve years.

"That the age limit within which a child should be vaccinated after birth should be six months."

The Sanitary Committee of the most numerously populated parish in England—that of Islington—has resolved to advise its vestry to petition the Local Government Board to supply two great defects in the Bill. The committee is moved in this matter by its medical officer of health, Mr. A. E. Harris. In a memorandum to his committee Mr. Harris expresses general approval of the Government Bill, including the repeal of the cumulative fines and the extension of the age limit. Such friendly feeling towards the Bill as a whole adds to the strength of the petition which the Sanitary Committee has advised the vestry to present in favour of certain amendments. The following are the resolutions of the Sanitary Committee:—

"Resolved that the vestry be recommended to petition the Local Government Board in favour of parents and guardians being required to have their children revaccinated when they arrive at a period of life between ten and twelve years of age."

"Resolved that the vestry be recommended to petition in favour of the transference of the administration of the Vaccination Acts from the boards of guardians to the sanitary authorities."

If the vestry of Islington adopts the recommendation of its Sanitary Committee it will set an excellent example to the sanitary authorities throughout the country.

THE PROPOSED PERMANENT FEVER HOSPITAL FOR CHISWICK.

WE have received a copy of the memorandum of objections to the proposed fever hospital for Chiswick, which memorandum has been submitted to the district council. While the objectors disclaim any objection to isolation they contend that a permanent hospital is unnecessary. There has been, they say, a steady and persistent decrease in the death-rate from scarlet fever, it having fallen from 0·98 per 1000 in 1860 to 0·24 per 1000 in 1890. Also in the county of Middlesex for the year 1895 the deaths from scarlet fever were in hospital districts 0 130 per 1000 and in non-hospital districts 0·0703. The latter argument, we must confess, fails to impress us, since it is clear that the incidence of scarlet fever on any one district must vary from year to year, and an outbreak in one hospital district might very materially influence the figures for the whole of the hospital provided districts. Furthermore it is to be expected on general principles, though we are not familiar with all the conditions obtaining in the urban districts of Middlesex, that hospitals are provided in those districts most likely to require them—i.e., in or for populous localities where the chances of infection are considerably greater than in more sparsely populated urban districts, and this fact alone would tend to increase the incidence of the disease on the districts in question. While, too, sympathising with the ratepayers in reference to a prospective increase in their rates we feel compelled to point out that experience goes to show the superiority of *permanent* buildings over those termed *temporary*. The latter are difficult to keep either cool in summer or warm in winter, they rapidly become dilapidated, and, what is a most important issue, they are never popular with the patients. Two points with all isolation accommodation are to make it non-repellent, so that persons in an infectious condition may not avoid it, and to have it in readiness beforehand. The proposed site, between the junction of two railways, does not sound restful, though it has to be admitted that certain of the Metropolitan Asylums Board Hospitals are

very near to railways. The fact of a board school being near the site would not in our opinion, unless it is proposed to use the hospital for small-pox, militate against it. There is no evidence indicating that hospitals other than those used for small-pox are detrimental to the surrounding population.

THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL.

WE are authorised to say that there is no truth in the statement recently widely circulated in the lay press—namely, that the election of Sir William Turner as President of the General Medical Council would involve his resignation of the Chair of Anatomy at Edinburgh University and also his taking up his residence in London. No conditions were attached by the Council to his appointment as President.

"A QUESTION OF FRANCHISE."

IN a recent leading article we referred to the fact that the Corporate and Medical Reform Committee had presented a petition to the Council of the Royal College of Surgeons of England claiming that the right of electing a representative of the College on the General Medical Council belonged to the Fellows and Members of the College and not to the Council and asking the Council to receive a deputation on the subject. The Council of the College have replied that they "see no reason to alter the mode of election which has been in force for the last forty years and consider that no useful purpose would be served by receiving a deputation." A protest against this action of the Council is being prepared by the petitioners for signature.

SMALL-POX IN MIDDLESBROUGH, KENTUCKY, U.S.A.

IT is a remarkable coincidence that small-pox is epidemic in Middlesbrough, Kentucky, U.S.A. An account of the epidemic is published in the official Public Health Report of the United States for the week ending March 25th, 1898. The disease was imported from Birmingham, Alabama, and the first case occurred in October, 1897. The State Board of Health took charge of the epidemic on Feb. 28th, 1898, declaring the disease epidemic, and since that time there have been 169 cases and 2 deaths to March 14th, 34 of the cases being those of white men and 135 those of negroes; one of the latter was that of a child one day old, the eruption appearing at the same time on mother and child. On March 13th there were 49 cases of variola and 23 suspects in the pest-house and 400 suspects quarantined at their homes. The population numbers about 4200 and about half are negroes. The town, we are told, "has been absolutely quarantined since Feb. 28th, no one being allowed either to enter or leave it. Sixteen guards, one day and one night, guard each of the eight roads leading to the town, and no tickets are allowed to be sold either to or from the town and practically there is no travel. Since the Board of Health took charge 1960 people have been vaccinated and forcible vaccination is still progressing. ..... Middlesbrough was a 'boom' town started some ten years ago and several million dollars were invested here in various enterprises. In two or three years the 'boom' collapsed and left the town stranded with a heavy debt. When this epidemic came it found the town without a dollar in the treasury. The place is practically owned by two or three companies and everybody works on a salary. These companies paid up their taxes in advance and, all having been expended, there were no funds for the city to draw on. The county, which is also heavily in debt, has been haggling with the city in regard to an appropriation, but none has been made. The city script is worthless and the grocer who has been furnishing the supplies refuses longer to accept it. The physicians and guards are practically getting no pay. Under these circumstances the State Board of Health threatened to withdraw all guards and physicians and quarantine the entire county unless the county provided funds to care for the epidemic." On March 14th, the day of the report, the patients were without food. "Numerous little towns and villages within a radius of twenty miles have instituted 'shot-gun' quarantine, and will allow no one to enter or leave them, though they have no small-pox in them. ..... Some of these places will not allow anyone to get off the train."

THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

THE festival dinner of this institution (of which Her Majesty the Queen is a patron and the Lord Mayor of London the president) was held at the Hotel Cecil on Wednesday, April 20th, Sir Edwin Durning Lawrence, Bart., M.P., the treasurer, presiding. Situated as it is in the Waterloo-bridge-road this hospital naturally ministers to the medical and surgical needs of large numbers of the poor women and children of South London. The number of in-patients amounts to some 486 yearly, while the average number of beds occupied is 44. The yearly average attendance of out-patients is over 8000. This means a large expenditure and it is earnestly to be hoped that there will be a hearty response to the appeal of the committee for funds. In proposing the toast of the evening the chairman said that "in many respects the south side of London was the poorest. In Lambeth especially there were many cases of real misery, more so than in East London, but the ordinary income of this hospital was barely enough to support the institution for a third of the year. If the public only realised the value of the services which the hospital rendered to the south of London greater support would be forthcoming." Mr. J. F. Eastwood, the treasurer, supported the chairman's earnest appeal, remarking that the hospital required at least £2000 more a year in annual subscriptions. Subscriptions to the amount of nearly £700 were announced by the secretary in the course of the evening. The health of the chairman was proposed by Dr. Septimus Sunderland and some compliments to the press terminated the proceedings of an interesting evening.

THE POLLUTION OF THE RIVER BRENT.

THE pollution of the River Brent is again exciting the interest of those who live in what has been described as the "healthy and pleasant neighbourhood" on its banks, and Mr. W. L. Williams, chairman of the Financial Committee of the Hanwell and Urban District Council, has written to the *Times* to state his views as to the course which should be adopted to lessen or abolish the nuisance which it must be admitted exists at the present time. The general question of the purity of the streams which discharge into the Thames is one of very great importance to the people of London as well as to those who live in the immediate neighbourhood of the streams themselves. At the present time the Brent is not the only tributary of the Thames which is grossly polluted. The Lee and the Wandle are both in a disgraceful state. It is a good and hopeful sign that people on the boards of local authorities are beginning to take some intelligent interest in the matter of the pollution of the streams in their districts. The difficulties which have to be overcome in preventing pollution are not small, while unfortunately the conflicts between neighbouring sanitary authorities often cause much delay in carrying out reforms. No reform can be easily carried out without a

general consensus of opinion in its favour and we always welcome the awakening of public opinion in a district in favour of improved sanitary conditions. In the case of the Brent the chairman of the Hanwell County Council makes some practical suggestions for the remedy. He thinks, in the first place, that the Thames Conservancy Board should stop the pollution of the stream by the addition to it of crude sewage. In the second place he suggests that strict supervision should be exercised over the effluents of the sewage farms which discharge into the stream. His third suggestion is that should these suggestions not be carried out a sewer should be constructed through the whole course of the Brent Valley to convey from the district the matter which now causes so much nuisance. With regard to the third proposition, however, no suggestion is made as to the ultimate destination of the sewage conveyed. We make no attempt to deal fully with these suggestions, but there can be no doubt that crude sewage should not be discharged into the rivers, that sewage effluents require strict supervision, and that the state of some of the sewage effluents which discharge into streams near London constitute an absolute disgrace to the responsible sanitary authorities.

THE ASSOCIATION OF PUBLIC VACCINATORS.

THE following have been elected to form the Council of the above. Mr. C. C. Claremont (St. Pancras), Dr. T. Cotton (Islington), Dr. S. Hague (Camberwell), Mr. V. A. Jaynes (St. Olave's), Mr. J. Loane (Whitechapel), Mr. F. H. Oliver (Shoreditch), Mr. J. F. Staines (St. Giles's), Mr. A. G. Wells (Fulham), Dr. A. E. Cope (St. George's), Mr. E. C. Greenwood (St. Marylebone), Dr. C. Lloyd Jones (St. Saviour's), Dr. G. A. Miskin (Lambeth), Dr. J. T. Rowland (Chelsea), and Mr. M. Townsend (Kensington). President: Mr. E. C. Greenwood. Vice-Presidents: Dr. E. Robinson (Birmingham), Mr. T. Garrett Horder (Cardiff), Mr. Wm. Skinner (Sheffield), and Dr. Frank Hawthorn (Newcastle-on-Tyne). Treasurer: Dr. G. A. Miskin (Slade House, 173, Kennington-road, S.E.). Secretaries: Mr. V. A. Jaynes (157, Jamaica-road, S.E.) and Dr. A. E. Cope (28, Bessborough-gardens, Westminster, S.W.). The President of the Local Government Board has promised to fix a day before the committee stage of the Bill is reached to hear the views of the public vaccinators on the proposed changes in the law. The honorary secretaries will be glad to receive any press-cuttings or statements of personal experience which will help the deputation in representing their case before Mr. Chaplin. The recommendations of the Council are now printed and may be had on application to the secretaries, to whom also the annual subscription of 5*s.* may be paid. It is highly desirable that the association should be representative of as many public vaccinators as possible. We have received a copy of "Suggestions and Recommendations in view of the Vaccination Bill now before Parliament," drawn up by the association, upon which we propose to comment in a future issue.

THE PLUMBERS REGISTRATION BILL.

THE amended draft of this Bill will, it is hoped, remove the regrettable opposition which the Bill has hitherto encountered. It is deserving of notice that the Worshipful Company of Plumbers have shown an unusual amount of public spirit in its promotion and of tact in their endeavours to overcome opposition and to present an effective measure thoroughly in accord with the wishes of the plumbing trade as a whole, while at the same time one which should meet the susceptibilities of other existing bodies interested in technical education. In a measure of this kind unanimity is essential to success, and powers are to be granted to the proposed council to accept the examinations of certain approved bodies as qualifying for registration, provided—and this is a most important clause—that such examinations shall include practical tests of workmanship in addition to theoretical knowledge. Exception was taken last year to the constitution of the proposed general council and to its assumption of educational functions, which objections are met by the present Bill. The council in the present Bill is composed of master and operative plumbers elected under regulations of the respective Local Government Boards of England, Scotland, and Ireland, while power is given to the council to appoint members from various sanitary, architectural, and other bodies, the following being mentioned in the schedule: the Incorporated Society of Medical Officers of Health; the Royal Institute of Architects, Ireland; the Royal Institute of British Architects; the Royal Institute of Public Health; the Sanitary Association of Scotland; and the Sanitary Institute, London. A measure the object of which is one so closely associated with the improvement of the public health is deserving of support from all sections of politicians. Unfortunately it is difficult to get the plumber taken seriously. He has so long been a target for weak and threadbare jokes that the most modest of wits is tempted to have a passing shot at him. It might, however, be well to bear in mind that there are hundreds of these men at work throughout the country the result of whose daily labours means health or sickness, life or death, to thousands of their fellow creatures annually. The desirability of ensuring in them some measure of efficiency may surely be considered a matter worth serious attention.

A COURSE of lectures on Diseases of Tropical Climates will be delivered by Dr. Patrick Manson, Lecturer on Tropical Medicine to the School, in the Medical School of St. George's Hospital, on Tuesday, May 17th, and every succeeding Friday and Tuesday, till July 22nd, at 5 P.M. each day. The course is intended for medical men about to practise in the Tropics or in Eastern Asia. Cards of admission may be obtained from Dr. Isambard Owen, the dean of the school.

WE learn that the members of the council of Charing-cross Hospital have recently decided to establish a Roentgen Department on an extensive scale. Mr. Mackenzie Davidson, whose work in this branch of science is well known, has been appointed to take charge of the department. Rooms in immediate proximity to the operating theatre of the hospital have, we understand, been set aside for the purpose.

THE annual dinner of the Army Medical Department will be held on Monday, June 13th, at the Whitehall Rooms, Hôtel Métropole, at 7.45 P.M. All communications should be addressed to Brigade-Surgeon-Lieutenant-Colonel J. Hector at 135, Brigstock-road, Thornton Heath, Surrey, who, as on previous occasions, is undertaking the duties of the organisation.

AT the annual dinner of old students of King's College, London, to be held at the Holborn Restaurant on Monday, June 13th, the Bishop of London will take the chair. All communications should be made to Mr. William Vincent, honorary secretary of the Dinner Committee, and addressed to King's College, London, W.C.

THE annual meeting of the Factory Girls' Country Holiday Fund, of which H.R.H. the Princess Christian is patron, will be held at the Mansion House to-day (Friday) at 3 P.M., when the Right Hon. the Lord Mayor, M.P., will preside.

THE annual meeting of the Children's Fresh Air Mission will be held in the Court House, St. Andrew-street,

Holborn-circus, on Thursday, April 28th, at 4 P.M. Mr. Walter Hazell, M.P., will preside.

HER MAJESTY THE QUEEN, who is the Patron of the Royal Hospital for Diseases of the Chest in the City-road, has contributed £25 to the Festival Dinner Fund.

WE are able to state that the recent differences with the honorary medical staff which have existed at the Royal Hants County Hospital, Winchester, have been satisfactorily adjusted.

H.R.H. THE PRINCESS OF WALES will open the new laboratories of the London School of Medicine for Women in Handel-street, Brunswick-square, next July.

THE ROYAL COMMISSION ON TUBERCULOSIS.

(PRELIMINARY NOTICE.)

THE report of the Royal Commission on Tuberculosis was laid on the table of the House of Commons on Tuesday evening. By the terms of reference the Commissioners were to inquire into what administrative procedures are desirable for controlling the danger to man of using as food the flesh and milk of tuberculous animals, and what should be the action of responsible authorities in condemning as food-supplies animals or carcasses of animals which exhibit a tuberculous condition. With such wide terms it will readily be seen that the report must not be dealt with in a summary manner, but on every side the evidence taken by the Commissioners as well as their recommendations will call for careful consideration. The Commissioners heard witnesses from the principal cities and counties and from the butchers' and farmers' societies all over the kingdom, and also visited the principal slaughter-houses and dairies, in addition to which many visits were paid to similar institutions on the continent for the purposes of obtaining information and making valuable comparisons. Two or three of the principal conclusions at which the Commissioners have arrived as the result of their labours may be mentioned. They record their sure belief that the contamination of milk plays far the greatest share in the infection of man by tuberculosis through his food-supply, while they consider that the inspection of the milk in this country amounts practically to nothing at all. With regard to meat inspection they find that its value varies (as would be expected) with the class of men employed as inspectors, Edinburgh being particularly fortunate in possessing the most competent staff. The Commissioners are satisfied that in the hands of a competent veterinary surgeon tuberculin is a well-nigh infallible test for tuberculosis and lay stress on the facts which they have been able to elicit with regard to the possibility of eliminating tuberculosis from infected herds.

We may briefly refer to some of the more important recommendations. With regard to slaughter-houses it is recommended that public slaughter-houses should become obligatory in urban districts, and that all carcasses should be examined by inspectors and stamped if they are passed as sound. Meat slaughtered elsewhere than in a public slaughter-house and brought into an urban district for sale must undergo inspection, while to avoid the sending of diseased animals into rural districts to be slaughtered it is proposed that the County Councils and analogous authorities in Scotland and Ireland should make arrangements to inspect the meat sold in villages.

The Commissioners recommend that in future no person be permitted to act as a meat inspector until he has passed a qualifying examination on the signs of health and disease in animals, dead and alive, which are destined for food, as well as on the rough anatomy of the body. They recommend that the Local Government Board should issue full instructions to the inspectors as to the seizing of carcasses, and they suggest that until such instructions are issued the entire carcass should be seized (*a*) when there is miliary tuberculosis of both lungs; (*b*) when tuberculous lesions are present on the pleura and peritoneum; (*c*) when tuberculous lesions are present in the muscular system, or in the lymphatic glands embedded in or between the muscles; and (*d*) when tuberculous lesions exist in any part of an emaciated carcass. But (*a*) when the lesions are confined to the lungs and the thoracic lymphatic glands, (*b*) when they are confined to the liver, (*c*) when they are confined to the pharyngeal lymphatic glands, or (*d*) when they are confined to any combination of the foregoing but are collectively small in extent the carcass, if otherwise healthy, need not be condemned, but every part of it containing tuberculous lesions must be seized. But any manifestation of tuberculosis in the pig is sufficient to warrant the seizing of the whole carcass.

With regard to milk it is recommended that notification of all diseases of the udder should be made compulsory; that milk vendors should be required to supply information as to the source of their milk upon the demand of the local sanitary authority; that all cowsheds and byres should be registered and that for the future they should not be permitted within 100 ft. of any dwelling house; and that all cowsheds should be properly floored, drained, and supplied with water for flushing purposes and be constructed in accordance with definite rules as to cubic contents of air, as to light and as to ventilation.

With regard to the elimination of bovine tuberculosis the Commissioners recommend that stock-owners be encouraged to test their animals by the offer of a gratuitous supply of tuberculin and the gratuitous services of a veterinary surgeon, the expenses entailed being defrayed by the Board of Agriculture in England and Scotland, and by the Veterinary Department of the Privy Council in Ireland. It is, however, to be made a condition that tuberculin is to be supplied only to such owners as will undertake to isolate reacting animals from healthy ones.

THE WORKMEN'S COMPENSATION ACT, 1897.

THE following memorandum, dealing with the appointment of medical referees, was issued during the week from the Home Office:—

The Secretary of State proposes shortly to proceed to appoint medical referees under the Workmen's Compensation Act, 1897.

Duties.—The principal duty of the medical referees will be to act as the advisers in medical matters of the committees, arbitrators, and county court judges, who are empowered to decide all questions arising in proceedings under the Act. For this duty they will be paid by the Treasury.

The ordinary procedure will be as follows. If after hearing the evidence brought by both sides doubt remains upon some medical point material to the case the committee, arbitrator, or judge may at their discretion make a reference to the referee directing him to examine the injured workman and to make a written report on a specified question or questions. As a rule the applicant will be required to attend the referee for examination at a time and place to be fixed by the referee; but in some instances, where the workman is unfit to travel, it will be necessary for the referee to visit him. In all cases the referee will make, in the first instance, a written report answering the question or questions propounded by the committee, judge, or arbitrator. Only in cases of special difficulty, before a county court judge or county court arbitrator, will the referee, after his written report has been considered, be asked to attend at a subsequent hearing to be held at a day and hour fixed by arrangement with him.

There will further be some cases in which applications will be made to the medical referees directly by the workmen. In certain circumstances a workman who is in receipt of an allowance under the Act is entitled to submit himself for examination to a referee for the purpose of obtaining a certificate as to his condition, which will be conclusive evidence in an arbitration under the Act.

Distribution of appointments.—The appointments will be made according to the county court circuits, referees being appointed for each of the 55 circuits into which England and Wales are divided. According to the circumstances of each

circuit it will either be subdivided and one or more of the referees assigned to each district, or arrangements will be made by which the referees will take the cases arising in the circuit according to a fixed rota. This arrangement will not, however, be binding on the county court judge or county court arbitrator, who is left free in each case to select such of the referees for the circuit as he sees fit, though he will probably in many cases be guided by the general arrangement.

Similar arrangements will be made for Scotland and Ireland, but the details are not yet settled.

In the first instance it is probable that only one or two referees will be appointed for some of the circuits, the ultimate arrangement being left to be determined when experience shows what is the number and distribution of the cases arising under the Act. For the same reason all appointments made will, in the first instance, be provisional and subject to revision if experience of the working of the Act should show that any rearrangement of duties or of the mode of payment is required.

Qualifications.—The Secretary of State, accepting and fully concurring in the recommendations of a committee appointed by him, which has examined the whole subject with great care, and has had the advice both of county court judges and of high medical authorities, deems it essential that the referees should be men of independent position and high standing in their profession so as to command the confidence of all parties in disputes under the Act; and should, moreover, have such experience of the class of questions arising as will enable them to decide with authority points in which there may be divergence of medical evidence.

Other things being equal, preference would therefore be given to those holding important hospital appointments or having had other special opportunities of gaining wide experience of accidents and their consequences, and to those who are not closely identified, by the nature of their practice or otherwise, with the classes affected by the Act.

Most of the cases arising under the Act will be of a surgical character and the majority of the referees must therefore be selected with special regard to this circumstance, but the Secretary of State will, where necessary, make provision also for cases of other kinds, whether purely medical or involving questions in the ophthalmic or other special branches of practice.

Fees.—The following scale of fees has been approved by the Treasury:—

For a first reference, to include examination and written report	2 guineas.
For a further written statement on the same reference	1 guinea.
For a second or subsequent reference in the same case	1 guinea.
For attendance at the proceedings on the request of a county-court judge or county-court arbitrator at a time and place to be arranged	3 guineas.

Where the medical referee has to travel to a place distant more than two miles from his residence there will be a further fee calculated at the rate of 5s. for each mile of distance. The Secretary of State may in some cases fix a "centre," other than the referee's residence, from which distances are to be measured.

The fee for the examination of a workman in receipt of an allowance, who submits himself voluntarily, is payable, not by the Treasury, but by the workman, who may be required to pay a reasonable fee before the examination is made.

Applications for the appointments should be addressed to the Home Secretary and should be sent under cover to the Private Secretary to the Secretary of State, Home Office, London, bearing on the envelope the words "Medical Referee," and should state the applicant's qualifications, age, &c., his residence, and the county court circuit to which he wishes to be attached.

Home Office, April 19th, 1898.

SOCIETY FOR THE STUDY OF INEBRIETY.—The annual meeting of this society was held in London on April 14th, the President, Dr. Norman Kerr, being in the chair. Lady Elizabeth Biddulph, who had just returned from Egypt, stated that the battle of Atbara had been fought without alcohol.—Dr. R. W. Branthwaite read a paper on Some Points in the Treatment of Inebriety, Surgeon-Lieutenant-Colonel Pringle, Surgeon-Major Poole, Dr. Longhurst, Dr. Hazell, Dr. A. Smith, Dr. James Stewart, Mr. Riley, and others taking part in the discussion.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE eighteenth meeting of the Royal Commissioners was held at the Council Chamber of the Westminster Town Hall on April 18th. At the commencement of the proceedings all the Commissioners were present with the exception of the Right Hon. J. W. Mellor and Sir John Dorrington. Mr. Cripps, Q.C., left soon after the commencement of the sitting and Sir George Barclay Bruce was not present after the luncheon adjournment. The whole of the sitting was occupied by the examination of the City Remembrancer.

The evidence given referred to the charges made by the New River Company to the citizens of London for the water they supplied and the witness later sketched a scheme of control which a committee of the Corporation of the City of London thought might be worthy of the attention of the Commissioners. Towards the end of the sitting evidence was given with regard to the sinking fund which is invested in the water companies' stocks by the Chamberlain of the City of London.

With regard to the charges the CITY REMEMBRANCER mentioned the case of a bank of which the rateable value was £5167; the charge made for water by the New River Company was £97 16*s.*, while the charge they were authorised to make was stated to be £155. Another case was given in which the rateable value was £3522. At 3 per cent. the water rent amounted to £105, but the Company entered into an agreement to supply the premises for an annual sum of £70 13*s.* The amount paid by the customers in the City of London was a matter of negotiation. Each case, the witness believed, was treated on its merits and no special fixed abatement was made. In answer to the CHAIRMAN the witness stated that he could not say how much was paid in water-rents by the citizens, that he did not know what amount was saved annually by the deductions in the water-rents made by the special bargains between the customers and the New River Company, and that therefore he was unable to say how much more the citizens would have to pay if the charges were levied at the full rateable value, as they are in the case of people living in other parts of London. The witness was unable to give the price paid by the citizens per 1000 gallons of water supplied. The City of London held that an equalisation of water-rents would be disadvantageous to all those parts of London in which the rateable value was high and the population comparatively low. At the present time a very large amount of money was paid by the City of London for the benefit of other districts. The City paid one-eighth of the total rates. No less than £214,705 a year were paid to the School Board, £107,000 a year were paid to the Metropolitan Common Poor Fund, and £104,073 were paid for the "equalisation of rates" for expenses incurred under the Public Health (London) Act of 1891.

In answer to Mr. DE BOCK PORTER the witness said that from the point of view of the citizens the amount which they would have to pay for water was the most important point which they had to consider, and they were of opinion that the results of purchase would in that respect be disadvantageous to them. It was a general opinion in the city that the New River Company treated the water consumers reasonably and fairly in the matter of the charges made. The City Corporation, however, would favour the adoption of a special water rate for offices and banks if such an arrangement could be carried out in a fair manner. In answer to the CHAIRMAN the witness said that it had occurred to the Corporation to negotiate for the purchase of the New River Company. He did not think that the City authorities would have any objection to his saying why the negotiations had failed, but he objected to answer the question without the consent of the representatives of the New River Company.

Mr. POPE, Q.C., who appeared for the New River Company, said he did not know to what the witness was referring.

The CITY REMEMBRANCER said that the negotiations for purchase to which he had referred were carried on some years ago before he held his present office and that a "personal element" had entered largely into the matter, so that he did not feel justified in giving further information on the subject. With regard to the purchase of the water companies'

undertakings, if they could be bought at a reasonable price and if the Corporation of London could ensure in advance that they would be fairly represented in the management of the water-supply and ensure a satisfactory rate of water rents for themselves, they would prefer purchase to control; but if the price paid were extravagant or the Corporation were not sufficiently represented in the management of the supply they would prefer control. With regard to control the witness suggested that the companies should be grouped. For this purpose he suggested that of the companies north of the Thames the New River and the East London companies should form one group, and the West Middlesex, Grand Junction, and Chelsea companies a second group. On the south of the Thames the Southwark and Vauxhall and the Lambeth companies should be united and the Kent Waterworks company left to supply its own district. Each group should be managed by a Board of Control elected on a basis of population and of rateable value. The witness suggested that the companies should combine voluntarily. This scheme, the witness said, had been considered by a committee of the Corporation and not by the Court of Common Council. The powers which it was suggested the Board of Control should have would have reference to the storage capacity of the reservoirs, to the purity of the supply, and to the pressure at which the water was supplied. It would be necessary for each area to have its own water examiner. The Board should have the power at present possessed by the official auditor of accounts and power to appeal to the Railway Commissioners. The witness suggested that each board should consist of about 48 members and that they should not be paid. He said that these suggestions were not to be considered as a "cut-and-dried policy." The Corporation of London had not understood that they were expected to come before the Commission pledged to any particular policy. The scheme which he had sketched was, he was instructed, thought worthy of consideration, but the proposals as he had stated them were not arranged in a final form.

After the adjournment evidence was given with regard to the sinking fund. The witness could not give definite information as to the exact amount of the different stock which was held. A list of the securities was promised.

On behalf of the London County Council Mr. BALFOUR BROWNE cross-examined the witness with regard to the relations which had existed between the City and the London County Council, with regard to the proposal that the companies' undertakings should be purchased, and with regard to the details of the scheme of control which the witness had suggested.

A REPORT OF THE RESULTS OBTAINED IN THE WEEKLY USE OF GLYCERINATED CALF VACCINE DURING THE YEAR 1897.

BY the courtesy of Mr. Thomas Bond, surgeon, A Division, Metropolitan Police, we have been enabled to inspect a statement showing the failures experienced by him in his weekly use of glycerinated calf lymph during the whole of the year 1897. In order to render the work more reliable and therefore more valuable a supply of vaccine from a source not before supplied to him was, as a rule, the first used in the morning's work, so that men in whom it failed (if any) should not be again attempted a second time with the vaccine which had previously failed. This arrangement not only tended to render the system of revaccination by Mr. Bond as effective as possible, but really placed the vaccine itself upon trial and confirmed the quality of the vaccine used by the only reliable test—actual trial by human vaccination—for however good vaccine appears to be when gathered the result in actual use is the only test of its real character.

Mr. Bond's regulations are that the vaccination of each man shall be attempted. The inspection of the men takes place upon the same day of the week following the vaccination and the facts brought to notice by those inspections are certainly interesting and instructive. A number of men vaccinated from the same calf will appear, some of them having typical vesicles in each place of insertion; then one man will show no signs of vaccination of any kind who upon inquiry will almost certainly prove to have been revaccinated in the army and fully protected. Such cases appear under P. in the statement, but if the man who has shown signs of insusceptibility is not considered insusceptible he is again attempted from some vaccine not before used, and if another failure follows he is justly considered protected provided the vaccine used in the second attempt proved itself active upon others attempted with him at the time of that second trial. But supposing the second attempt produces a satisfactory vaccination the case appears as a failure in the first attempt under F. These cases of failure are of course rare, for vaccination from vaccine having failed which was proved so thoroughly effective upon others at the time of the first attempt, it is not reasonable to expect a second similar attempt could succeed unless the failure was due solely to some accident in the operation.

The percentage of failures is calculated by deducting from the number attempted (M.) the number protected (P.), the remainder, = R, being considered the number susceptible and $\therefore \frac{F}{R} 100$ = percentage of failures. On reference to the statement it will be seen that the greatest number of failures was from a vaccine aged 46–53 days. Of vaccine of this age one lot came from Calf No. 18, giving M. 10, S. 3, P. 1, F. 6 in May. The other lot came from Calf No. 66 in December, gave M. 4, S. 3, P. 1, F. 9, so that the percentage of failures with vaccine of the age in question was as seen in the summary. The vaccine tried in May had previously been tried in April with uniform success.

The summary of the statement shows 2·19 per cent. of failures from 898 revaccinations attempted during the year. An analysis shows that glycerinated calf vaccine has been produced which will remain equally active throughout the whole year and which is not injuriously affected by the heat. We understand that the arrangement now in operation will be continued to the end of the present year.[1]

Tabulated Statement, Summary of Totals, &c.

Age of vaccine at trial.	M.	S.	P.	F.	Percentage of failures.
1 to 7 days	93	78	15	—	—
8 ,, 14 ,,	189	157	31	1	0·63

Totals	898	757	124	17	2·19

Total attempted (M.) 898
Deduct total protected (P.) 124
774

Total failed (F.) = 17.

$\therefore \frac{1700}{774}$ = 2·19 per cent.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on April 14th, the President, Sir WILLIAM MACCORMAC, Bart., being in the chair.

The report of the Jacksonian Committee was received and adopted and the Council awarded the Jacksonian Prize to Mr. Percy Furnivall, F.R.C.S. Eng. The subject was "The Pathology, Diagnosis, and Treatment of the Various Neoplasms met with in the Stomach, Small Intestine, Cæcum, and Colon." The Collegial Triennial Prize was not awarded. The Jacksonian Committee submitted two

[1] The vaccine used was obtained from the Association for the Supply of Pure Vaccine Lymph.

subjects for the Jacksonian Prize in 1899 and the following was adopted: "The Pathology, Diagnosis, and Treatment of Inflammatory Affections of the Nasal Fossæ and the Associated Sinuses and Air Cells." The Council decided that the subject for the next Collegial Triennial Prize should be: "The Thyroid Gland—its Structure, Comparative Anatomy, and Physiology."

A report from the Committee of Management was received and adopted; it contained a recommendation that Winchester College should be added to the list of institutions recognised as places of instruction in chemistry, physics, and practical chemistry, and it also contained a recommendation that the time spent on the study of chemistry, physics, practical chemistry, and biology in a recognised institution should be allowed to count as part of the first year of professional study.

A report from the Committee on the Midwives Registration Bill was received and approved; it was as follows:—

The Committee, having carefully considered the Bill, are of opinion that it does not provide sufficient protection to lying-in women and adequate safeguards in the interest of the public health, and accordingly recommend that the Council should not give it their support.

The Council directed that Mr. J. Rowland Humphreys, honorary secretary of the Midwives Bill Committee, should be informed of the decision at which the Council had arrived.

It was also resolved that a special meeting of the Council should be held on Wednesday, May 4th, at 3 P.M., to consider the report of the General Medical Council on the Midwives Bill.

A letter was read from Mr. Francis Fowke, general secretary of the British Medical Association; it was accompanied by documents relating to the Midwives Bill, but their further consideration was postponed.

The PRESIDENT, on behalf of himself and the vice-presidents, reported that they had taken into consideration the petition from Members of the College resident in Italy on the subject of the proposed legislation of the Italian Government respecting the practice of medicine and surgery by foreigners, and that they had drawn up a letter on this subject to be sent to the Secretary of State for Foreign Affairs. The letter was approved and it was agreed that the petitioners should be informed of the steps which had been taken.

The Council proceeded to the further consideration of the petition from certain Fellows and Members of the College, claiming that the right of electing the Representative of the College to the General Medical Council is, by Section 7 of the Medical Act, 1886, vested in the Fellows and Members of the College, calling upon the Council to make arrangements to hold an election and enable the Fellows and Members to choose a Representative, and asking to be received and heard in support of their petition. The Council resolved that the petitioners should be informed that the Council see no reason to alter the mode of election which has been in force for the last forty years, and consider that no useful purpose would be served by receiving a deputation from the petitioners in reference to their claims.

The Secretary stated that the appeal against the assessment of the College for corporation duty would probably be heard on April 25th.

The Council proceeded to elect to the Fellowship two Members of twenty years' standing, and Mr. Charles Sissmore Tomes, M.R.C.S. Eng., L.D.S., F.R.S., of London, and Mr. William Dunnett Spanton, F.R.C.S. Edin., M.R.C.S. Eng., of Hanley, were elected.

Mr. BANKS moved that the Council do take into consideration the question of authorising a special robe to be worn by the Fellows of the College. The matter was referred to a committee.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6629 births and 4201 deaths were registered during the week ending April 16th. The annual rate of mortality in these towns, which had been 21·5 and 20·2 per 1000 in the two preceding weeks, further declined last week to 19·5. In London the rate was 19·1 per 1000, while it averaged 19·8 in the thirty-two provincial towns. The lowest rates in these towns were 12·5 in Preston, 12·6 in Portsmouth, 13·6 in West Ham and 14·8 in Swansea; the highest rates were 24·6 in Oldham, 25·6 in Gateshead, 26·0 in Newcastle-upon-Tyne, and 27·5 in Liverpool. The 4201 deaths included 487 which were referred to the principal zymotic diseases, against 538 and 516 in the two preceding weeks; of these, 219 resulted from measles, 114 from whooping-cough, 69 from diphtheria, 33 from scarlet fever, 29 from "fevers" (principally enteric), 22 from diarrhœa and 1 from small-pox. No death from any of these diseases was recorded last week in Preston; in the other towns they caused the lowest death-rates in Plymouth, Salford, Burnley, and Blackburn; and the highest rates in Gateshead, Halifax, Cardiff, and Leicester. The greatest mortality from measles occurred in Leeds, Brighton, Wolverhampton, Bristol, Halifax, and Leicester; from scarlet fever in Derby; and from whooping-cough in Gateshead and Newcastle-upon-Tyne. The mortality from "fever" showed no marked excess in any of the large towns. The 70 deaths from diphtheria included 34 in London, 7 in Cardiff, 4 in West Ham, 3 in Croydon, and 3 in Birmingham. One fatal case of small-pox was registered in Newcastle-upon-Tyne, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment last week in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, April 16th, was 2384, against 2371, 2377, and 2421 at the end of the three preceding weeks; 217 new cases were admitted during the week, against 191, 239, and 234 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 451 and 372 in the two preceding weeks, further declined last week to 305, and were 81 below the corrected average. The causes of 75, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Manchester, Leeds, Hull, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Burnley, Bradford and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·2 and 24·1 per 1000 in the two preceding weeks, further declined to 22·5 during the week ending April 16th, but exceeded by 3·0 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·0 in Leith and 19·6 in Greenock to 23·8 in Perth and 30·3 in Dundee. The 680 deaths in these towns included 27 which were referred to whooping-cough, 17 to diarrhœa, 14 to measles, 11 to scarlet fever, 6 to "fever," and 4 to diphtheria. In all, 79 deaths resulted from these principal zymotic diseases, against 82 and 105 in the two preceding weeks. These 79 deaths were equal to an annual rate of 2·6 per 1000, which was 0·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 25, 21, and 44 in the three preceding weeks, declined again to 27 last week, of which 13 occurred in Glasgow and 5 in Edinburgh. The 14 deaths referred to measles showed a decline of 10 from the number recorded in the preceding week, and included 12 in Glasgow. The fatal cases of scarlet fever, which had been 7, 12, and 4 in the three preceding weeks, rose again to 11 last week, of which 7 occurred in Glasgow. The 6 deaths referred to different forms of "fever" exceeded the number recorded in any recent week and included 3 in Dundee; and of the 4 fatal cases of diphtheria 2 were registered in Edinburgh. The deaths from diseases of the respiratory organs in these towns, which had been 178 and 157 in the two preceding weeks, rose again to 164 last week, and slightly exceeded the number in the corresponding period of last year. The causes of 35, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 35·1 and 24·3 per 1000 in the two preceding weeks, rose again to 27·1 during the week ending April 16th. During the thirteen weeks of last quarter the death-rate in the city averaged 32·4 per 1000, the rate during the same period being 21·7 in London and 20·3 in Edinburgh. The 182

* Including 52 cases of membranous croup.

† Including deaths from membranous croup.

deaths registered in Dublin during the week under notice showed an increase of 19 upon the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 20 and 9 in the two preceding weeks; of these, 3 resulted from "fever," 3 from whooping-cough, 2 from scarlet fever, 2 from diphtheria, and not one either from small-pox, measles, or diarrhœa. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 2·8 in London and 1·8 in Edinburgh. The deaths referred to different forms of "fever," which had declined from 7 to 3 in the four preceding weeks, were again 3 last week. The 3 fatal cases of whooping-cough exceeded by one the number recorded in the preceding week. The deaths from scarlet fever, which had been 4 and 2 in the two preceding weeks, were again 2 last week. The 182 deaths in Dublin last week included 21 of infants under one year of age, and 56 of persons aged upwards of sixty years; the deaths of infants corresponded with the number recorded in the preceding week, while those of elderly persons showed an increase. Seven inquest cases and 4 deaths from violence were registered; and 85, or nearly one half, of the deaths occurred in public institutions. The causes of 5, or nearly 3 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1898.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during March in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7·4 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 9·8, 8·2, and 7·8 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. George Hanover-square, St. James Westminster, Stoke Newington, St. Giles, St. Martin-in-the-Fields, City of London, and Bermondsey; while they showed the largest excess in Fulham, Hackney, Holborn, Clerkenwell, Bethnal Green, St. Saviour Southwark, St. George Southwark, and Battersea. Three cases of small-pox were notified in London during March, corresponding with the number in each of the two preceding months; of these, 1 belonged to Holborn, 1 to Battersea, and 1 to Camberwell sanitary areas. One small-pox case was admitted to the Metropolitan Asylum Hospitals during March, but no patient remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a further decline from that recorded in the five preceding months; this disease was proportionally most prevalent in Fulham, Hackney, Clerkenwell, Limehouse, Newington, Rotherhithe, Battersea, and Lewisham sanitary areas. The Metropolitan Asylum Hospitals contained 2358 scarlet fever patients at the end of March, against 3507, 3021, and 2640 at the end of the three preceding months; the weekly admissions averaged 208, against 272, 232, and 214 in the three preceding months. The prevalence of diphtheria in London during March showed a decline from that recorded in the previous month; among the various sanitary areas this disease showed the highest proportional prevalence in Hackney, Holborn, Clerkenwell, St. Luke, St. Saviour Southwark, St. George Southwark, and Lee. There were 1009 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of March, against 1066, 1055, and 1042 at the end of the three preceding months; the weekly admissions averaged 129, against 151, 132, and 140 in the three preceding months. The prevalence of enteric fever in London slightly exceeded that recorded during February; this disease was proportionally most prevalent in St. Pancras, Hackney, Newington, and Greenwich sanitary areas. The Metropolitan Asylum Hospitals contained 64 enteric fever patients at the end of March, against 116, 106, and 84 at the end of the three preceding months; the weekly admissions averaged 12, against 17 and 11 in each of the two preceding weeks. Erysipelas showed the highest proportional prevalence in St. Giles, Bethnal Green, St. George-in-the-East, Poplar, and Wandsworth sanitary areas. The 25 cases of puerperal fever notified in London during March included 4 in Wandsworth, 3 in Battersea, 3 in St. Pancras, 2 in Kensington, 2 in Newington, and 2 in Lambeth sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, April 2nd, the deaths of 8970 persons belonging to London were registered, equal to an annual rate of 20·8 per 1000, against 21·3, 22·0, and 21·4 in the three preceding months. The lowest death-rates in the various sanitary areas were 14·4 in Stoke Newington, 14·7 in Hampstead, 15·4 in Lewisham (excluding Penge), 16·3 in Lee and in St. George Hanover-square, 17·3 in Wandsworth, and 17·6 in Hackney; the highest rates were 27·7 in St. Olave Southwark, 28·6 in Westminster, 28·7 in Strand and in St. Luke, 28·8 in Limehouse, 29·8 in City of London, and 31·6 in St. George-in-the-East. During the five weeks of March 1287 deaths were referred to the principal zymotic diseases in London; of these, 647 resulted from measles, 286 from whooping-cough, 205 from diphtheria, 63 from scarlet fever, 49 from diarrhœa, 35 from enteric fever, and 2 from typhus. These 1287 deaths were equal to an annual rate of 3·0 per 1000; the lowest zymotic death-rates were recorded in St. James Westminster, City of London, Newington, St. Olave Southwark, Camberwell, and Lee; and the highest rates in Hammersmith, Westminster, Islington, Bethnal Green, Woolwich, and Plumstead sanitary areas. The 647 fatal cases of measles were considerably more than double the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Hammersmith, Westminster, Islington, St. Giles, Bethnal-green, and Woolwich sanitary areas. The 63 deaths referred to scarlet fever were 18 below the corrected average number; the mortality from this disease was highest in Whitechapel, St. George-in-the-East, Rotherhithe, Battersea, and Plumstead sanitary areas. The 205 fatal cases of diphtheria were 24 above the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Holborn, Clerkenwell, St. Saviour Southwark, Battersea, Wandsworth, and Plumstead. The 286 deaths from whooping-cough were 60 below the corrected average number; the mortality from this disease was highest in Islington, Shoreditch, Bethnal Green, St. George-in-the-East, Limehouse, and Plumstead sanitary areas. The 35 fatal cases of enteric fever were within 6 of the corrected average number; the mortality from this disease showed no marked excess last month in any of the sanitary areas. The 2 deaths referred to typhus were of persons belonging to Kensington sanitary area. The 49 fatal cases of diarrhœa were 19 below the corrected average number. In conclusion, it may be stated that the mortality in London last month from these principal zymotic diseases was more than 30 per cent. above the average, owing principally to the excessive fatality of measles.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was last month equal to 141 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover Square, St. James Westminster, Stoke Newington, St. Martin-in-the-Fields, St. George Southwark, and Bermondsey; and the highest rates in Westminster, Holborn, Bethnal Green, St. George-in-the-East, Limehouse, and Lee.

THE SERVICES.

NAVAL MEDICAL SERVICE.

STAFF-SURGEONS: R. W. Anderson to the *Anson*; Alfred J. Picthorn to the *Galatea*, for temporary service; J. M. Rogers to the *Terror*, additional for service in Bermuda Dockyard; and J. Jenkins to the *Indefatigable*. Surgeons: Reginald T. A. Levinge to the *Humber* and H. N. Stevens to the *Excellent*.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant-Colonel Macdonald, Senior Medical Officer, Port Blair, is appointed to officiate as Medical Storekeeper, Bengal, during the absence of Surgeon-Lieutenant-Colonel Warden on plague duty at Bombay.

Surgeon-Captain E. Wilkinson is appointed to plague duty in the Jullundur District to assist Surgeon-Captain James.

VOLUNTEER CORPS.

Artillery: 1st Banff: Surgeon-Captain W. L. Stewart, M.D. Aberd., to be Surgeon-Major. *Royal Engineers* (Volunteers): — 1st Flintshire (Buckley): Surgeon-Lieutenant G. O. M. Lunt, M.B. Edin., to be Surgeon-Captain. *Rifle:* 3rd (Duke of Connaught's Own) Volunteer Battalion the Hampshire Regiment: Captain Harry Munyard Brownfield resigns his commission, and is appointed Surgeon-Lieutenant. 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Frank Alexander Wagstaff to be Surgeon-Lieutenant. 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry: Surgeon-Major D. Cowie, M.B. Glasg., to be Surgeon-Lieutenant-Colonel. 1st (Inverness-shire Highland) Volunteer Battalion the Queen's Own Cameron Highlanders: Surgeon-Lieutenant J. Dewar, M.B. Glasg., resigns his commission. 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Richard Ardra Fegan to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADE.

Mersey Brigade: Surgeon-Lieutenant-Colonel W. J. Fleetwood, M.D. St. And., 4th Volunteer Battalion the King's (Liverpool Regiment), to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade.

ROYAL PRESENTS TO THE ROYAL VICTORIA HOSPITAL, NETLEY.

The gifts which have been forwarded as a memento of the visit which Her Majesty and Princess Henry of Battenberg recently paid to the Royal Victoria Hospital have given great pleasure both to the officers of the medical staff and to the patients under treatment. On the occasion of her late visit the Queen inspected nineteen wards and for each of them she has sent her latest photograph bearing her autograph: "Victoria, R.I., 1837 — 1897. June 22nd, 1897." The photographs are handsomely framed in oak and gold and on a plate at the base of each is the inscription: "Presented by Her Majesty the Queen, 1898." With the photographs Her Majesty has also sent a fine portrait of the late Prince Consort, which has been framed in dark walnut with gold beading. Her Majesty's other gifts include engravings of herself in her pony carriage, the Jubilee procession passing Trafalgar-square, the Jubilee procession leaving Buckingham Palace, a group of the Royal Family, and some coloured prints. All of them have been framed in oak and gold, with the exception of the three coloured prints, the latter being in massive gilt frames, and each bears a brass plate with an inscription announcing the donor. When the Queen visited the wounded from the North-West frontier of India she requested the principal medical officer to order at her expense the best artificial limbs which modern invention has produced for those who have lost limbs in her service. In addition Her Majesty also ordered four invalid lounge chairs, which have duly arrived. They are of the latest pattern and most comfortable. The gift from Princess Beatrice is of a very pathetic nature, a gift of a soldier's widow to men who have fought for their country. It consists of a very fine steel portrait of the late Prince Henry of Battenberg and is framed in oak and gold. It bears the inscription: "Prince Henry of Battenberg, K.G., presented by Her Royal Highness Princess Henry of Battenberg." The pictures are to be hung on the walls of the wards of the hospital at an early date.

THE LATE CAMPAIGN ON THE INDIAN FRONTIER.

There seems every reason to believe that military operations against the Afridis have now really terminated and that the frontier tribes have submitted. Those of the British sick and wounded of the late campaign who are still remaining in India are doing well. It is highly probable that the conduct of this frontier war will form the subject of some Parliamentary inquiry and debate during the present session. It is a curious fact that the political officers appear to have been quite ignorant of the state of feeling among the tribes immediately before and up to the very time of their revolt. It is now apparently believed that if prompt measures had been taken at the beginning and troops had been sent to Ali Musjid, Lundi Khotal, and other posts along the Khyber Pass and on the western and southern borders of the Peshawar district when rumours of an intended movement on the part of the tribes first reached the authorities there would have been a highly probable chance of stamping out the rebellion in its initial stage.

THE TREATMENT OF ENTERIC FEVER IN INDIA.

According to the Anglo-Indian papers Surgeon-Major S. J. Rennie, in medical charge at Meerut, has been very successful in his treatment of cases of enteric fever with repeated doses of olive oil. A correspondent of the *Pioneer Mail* of March 25th last points out with reference to the foregoing that THE LANCET of Nov. 27th, 1897, p. 1383, contains an article by Dr. Owen F. Paget of Fremantle, Western Australia, on the value of olive oil in the treatment of this fever and the highly favourable results following its use in over 100 cases attended by him.

THE SOUDAN.

Further operations in the Soudan are suspended for three months. When the Nile rises and the railway has been carried further and the final arrangements for an advance on Khartoum have been made the campaign will be renewed. The moral effect of Sir Herbert Kitchener's brilliant victory must inevitably be great, but there will in all probability be some severe fighting before Khartoum falls into our hands, and the medical services of the Anglo-Egyptian force have not only plenty of work in the present but a good deal of prospective work before them.

ROYAL SCHOOL FOR ARMY OFFICERS' DAUGHTERS.

The annual meeting of this school was held on April 16th at the Royal United Service Institution, when the Duke of Cambridge presided. The report stated that the number of pupils on the rolls on Jan. 1st was 113. Among the donations which have been received was one of £1150 from Mr. J. A. Mullens, £750 of which have been devoted to the foundation of a Jubilee scholarship of £50.

SERVICE ON THE WEST COAST OF AFRICA.

Surgeon-Major C. J. Josling, Surgeon-Major R. G. Thompson, Surgeon-Captain W. T. Mould, Surgeon-Captain F. Smith,, Surgeon-Major A. A. Sutton, Surgeon-Captain J. W. Cockerill, and Surgeon-Captain G. Raymond have embarked for Sierra Leone for service in connexion with the operations on the west coast of Africa.

INOCULATION FOR PLAGUE.

Professor Haffkine is proceeding, in company with Surgeon-Lieutenant-Colonel Lawrie, to the plague-infected villages in the Nizam's territory in order to introduce his method of prophylactic inoculations on a large scale.

Brigade-Surgeon-Lieutenant-Colonel Sir A. S. Lethbridge, K.C.S.I., and Brigade-Surgeon-Lieutenant-Colonel D. D. Cunningham, C.I.E., have been granted the two extra pensions of £100 each available for the Bengal establishment for the year 1898-99, and Brigade-Surgeon-Lieutenant-Colonel F. H. Blenkinsopp and Brigade-Surgeon-Lieutenant-Colonel J. Arnott have been granted the pensions due to the Madras and Bombay establishments respectively.

The *Times* says: "The Admiralty have granted seven days' extra leave to all men in the Indian Defence Flotilla in consequence of the exceptional character of their services at Bombay during the plague epidemic. The hired transport *Jelunga*, which is due at Southampton on April 27th, has on board 276 ratings from Indian defence ships. She arrived at Suez on Saturday."

Major-General H. Trotter, commanding Home District, has consented to become a Vice-President of the Volunteer Medical Association and will dine with the Volunteer Medical Staff at Limmer's Hotel on May 4th; Colonel Mackinnon, A.A.G., and Surgeon-Colonel T. O'Farrell, P.M.O., have also accepted invitations.

Surgeon-Major-General Harvey, who is officiating as Director-General of the Indian Medical Service, recently visited Bombay to confer with the authorities regarding plague measures and subsequently proceeded on tour through Hyderabad, Baroda, Rajputana, and the Punjab.

In future when from the exigencies of service a surgeon-lieutenant-colonel is appointed principal medical officer of a general hospital in India of 500 beds he will be granted the temporary rank of brigade-surgeon-lieutenant-colonel.

Correspondence.

"Audi alteram partem."

"TRANSMISSION OF SYPHILIS TO THE THIRD GENERATION."

To the Editors of THE LANCET.

SIRS,—May I in the first place point out, in reply to Dr. G. Ogilvie's letter in THE LANCET of March 5th, that Fergusson's "personal observations" in Portugal regarding the curability of syphilis in all its stages without mercury were testified to by Rose and "numerous British surgeons" from personal observations in the Peninsular War and corroborated five years later by Rose in London when surgeon to the Coldstream Guards and to the St. James's Infirmary?[1]

2. The argument Dr. Ogilvie advances in discrediting "Ferguson and Lee" in the *British Dermatological Journal* of November, 1897, and again advances in THE LANCET of March 5th with respect to Fergusson—viz, that these observations "were made at a time when no distinction was drawn between syphilitic and other sores"—was anticipated by Rose and referred to by Mr. Lee himself. "It is reasonable," says Rose, "to think that a considerable part of the cases of which Mr. Fergusson speaks could not be regarded by cautious practitioners as venereal," but while admitting some of the cases he himself brought forward were not venereal in the Guards he concludes that "amongst a number of cases of such a description taken indiscriminately the probability of some being venereal is materially increased and must at last approach nearly to a certainty"; while "It is true," says Mr. Lee, "that at the time Mr. Rose conducted his experiments no clear distinction was drawn between those syphilitic affections which if left to themselves would infect the constitutions of the patients and those which would not, and therefore a great many sores were no doubt said to be cured without mercury which under no circumstances would have been followed by secondary symptoms. It is exceedingly probable, however, that a certain proportion of the cases treated by Mr. Rose really depended upon the infecting variety of the disease, and as Mr. Rose found that he could deal with these cases without administering mercury we can only conclude that the disease he was treating had appeared in some modified form such as Dr. Ferguson had noticed in Portugal and such as he states to have existed also in Germany and in Russia." Moreover, the differentiation between local and infecting disease had already been noted by Bell (1797), who observed "that a chancre might frequently be cured with external applications alone and as we know from experience that the virus is not always absorbed the cure would in a few instances prove permanent," while the controversy between syphilis and "syphiloid" disease existed in the days of Abernethy (1804) and must have been well known to Fergusson (1812). And in truth it is evident that Fergusson not only noted a distinction between the sores in the Portuguese and British but in the British themselves, and Dr. Ogilvie's quotation "that the disease in its primary state is curable in Portugal without mercury" when taken alone is misleading. By disease Fergusson referred to the ulcerations in the Portuguese, which he compared with the "trifling cases of chancre as we have seen at home which can often be dried up with a piece of lint" and the venereal ulcerations in the British which were "more intractable to the operation of mercury than under similar circumstances at home." The Portuguese ulcerations were either local, which "made me shudder to look at," cured by topical remedies, or followed by insignificant throat ulcers cured also by topical remedies. The British ulcerations were characterised by "extraordinary action," "the most melancholy of all mutilations," and "the constitution while strongly under the influence of the remedy (mercury) has become affected with the secondary symptoms in a proportion that could not have been expected."

That the primary disease was phagedæna in the Portuguese as well as the British Dr. Ogilvie admits. That it was syphilitic he does not admit, for he considers that Fergusson debarred himself from observing the natural cure of such cases without mercury by indiscriminately prescribing the drug. In proof of this Dr. Ogilvie adduces the case of the British officer as an example of the class of case in the British to which Fergusson's "observations chiefly refer." The diagnosis of this case, says Dr. Ogilvie, is "soft multiple phagedænic sores. He had not syphilis as far as the history of the case goes, and the administration of mercury, which was dictated by the patient's fears and Fergusson's responsibility, was unnecessary." This opinion is negatived by the following case recorded in Mr. Alfred Cooper's work on Syphilis: "The case was one of soft chancres of the penis rapidly running into phagedæna." It was cured by local treatment and hot bath immersion but "two months after the phagedæna an eruption of rupia appeared all over the body, not having been preceded by roseola or any other secondary manifestation; this again was followed after an interval of three years by symptoms of spinal disorder." Fergusson, as a matter of fact, narrated the case of the officer as an example of syphilis "in a local form of phagedænic ulceration, and ..... no doubt, so thoroughly had the specific contagion been superseded by the violence of the inflammation, would have healed safely without mercury." Carmichael, according to Rose, anticipated Dr. Ogilvie in regarding the disease which prevailed in Portugal "as a phagedænic or sloughing ulcer differing from syphilitic chancre and in which he has found mercury to be neither necessary nor serviceable." However, "in what manner that kingdom, overrun by every description of foreigner, has escaped introduction of syphilis itself is left entirely to conjecture."

3. With Dr. Ogilvie's conclusion, "there are many venereal sores which require no treatment by mercury and are not followed by general symptoms," I agree, but I do not agree that this is proof of the non-syphilitic origin in every case. While admitting that some soft sores do not owe their origin to syphilis I maintain that Fergusson and Rose demonstrated the fact that some do and that syphilis under certain circumstances does assume primarily the suppurating form of disease which may be local and non-infecting or may be followed by constitutional symptoms of a modified nature. In this respect I have only to refer at the present time to cases of urethritis in the male (not concealed chancre) and vaginitis in the female diagnosed and treated as gonorrhœa, which not infrequently at a later period and not truly secondarily are followed by modified symptoms; while Mr. Lee's description of local non-infective syphilitic ulcerations consequent on re-infection suggests the same consequent on hereditary partial immunity.

4. Dr. Ogilvie denies attenuation on the ground that "secondary symptoms frequently disappear without treatment"; but here again Fergusson's conclusion "that the anti-syphilitic woods combined with sudorifics are an adequate remedy for constitutional symptoms, the quantity of mercury being always insignificant and often altogether omitted," cannot be taken alone. By constitutional symptoms Fergusson not only referred to secondary throat symptoms treated and cured by local remedies but also to later lesions. "Amongst the Portuguese," says Fergusson, "dreadful examples of exfoliation and loss of parts no doubt sometimes occur, but these ..... by no means constitute a large proportion of the affected; on the contrary, the affection of the bones is often so slight that were it not that it could be traced through the preceding stages and that the nocturnal paroxysm of pain is distinctly marked it might be classed, treated, and cured as rheumatism with sudorifics alone." There seems nothing "vague" in that statement of tertiaries, as Dr. Ogilvie thinks. If Fergusson's account of the disease in Portugal is read[2] and the very different results in two classes of people exposed to the same sources of infection noted, the conclusion is irresistible that Fergusson was justified in regarding the disease the same in both—i.e., mitigated syphilis in the Portuguese as compared with that in the British, and mitigated in comparison with the description of the disease which scourged Europe "at the close of the fifteenth century." In explanation Fergusson advanced the theory of transmitted partial hereditary immunity. He supported it by the analogous mitigation of variola and other specific fevers through generations and their reactivity when transplanted into virgin soils. He compared this to "the same species

[1] Transactions of the Royal Medical and Chirurgical Society, vol. viii.

[2] Ibid., vol. iv.

of seed ..... sown upon the same ground until it shall so degenerate in point of vigour as to become almost incapable of reproducing itself, but let it be changed to any other of any kind, though even of far inferior quality, it will immediately display new powers of life and fructify and vegetate with its native strength." He advanced the alternative view of climate (malaria) and intemperance to account for increased virulence; either of which theories may apply at the present day. Rose, on the other hand, attributed mitigation to non-mercurial treatment, thus anticipating Neisser and Dr. Ogilvie in the theory of improved treatment.

5. If further we compare Dr. Ogilvie's statement that "altogether the utterances of this meritorious military surgeon are more remarkable for military determination than for medical discrimination" with Aitken's testimony in his "Science and Practice of Medicine," quoted by Mr. Hutchinson in his work on Syphilis, the difference is striking: "The surgeons of the British Army perceived the ravages of the combined poisons of mercury and syphilis and had the boldness to declare themselves against the system of treatment. The credit of this improvement is mainly due to (1) Mr. Ferguson .....; (2) to Mr. Rose .....; (3) to Dr. John Thompson, the first professor of military surgery." I am, Sirs, yours faithfully,

JOHN A. SHAW-MACKENZIE.

Grosvenor-street, W., April 13th, 1898.

"THE LATE MR. R. R. CHEYNE AND THE PRESERVATION OF VACCINE LYMPH."

To the Editors of THE LANCET.

SIRS,—As one who knew and very much esteemed the late Mr. R. R Cheyne, F.R.C.S., it is particularly gratifying to know that not only can the credit of having introduced glycerinated lymph be claimed by an Englishman, but that that Englishman was Mr. Cheyne. Had his method of treating vaccine lymph been generally adopted fifty years ago vaccination would probably not have fallen into disrepute with a section of the public, and many of the lives of victims to small-pox would in consequence have been saved. The knowledge of the antiseptic properties of glycerine is half a century old, but Mr. Cheyne not only proved the wonderful keeping powers of glycerinated lymph but also the excellent results that followed upon its use. We are much indebted to Dr. Copeman for increasing our knowledge as to why such lymph is more serviceable and safe for employment than that which has not been glycerinated, but the whole credit of pointing out that it was so lies with Mr. Cheyne, who, I have no doubt, if bacteriological methods had been as advanced in his day as they are now, would have furnished the scientific explanation.

Dr. Copeman says in his letter that "glycerine fifty years ago was by no means the pure chemical product which it is to-day, and, indeed, it has been suggested that its use as an addition to vaccine lymph has in former days been occasionally productive of mischief. This may possibly account for the late Mr. Cheyne's suggestion not having been generally accepted at the time." As a matter of fact Mr. Cheyne used glycerinated lymph invariably for many years in a very extensive practice and he always claimed uniformly satisfactory results. The real reason, I fancy, why the method was not more generally adopted was not the one suggested by Dr. Copeman, but because it was new and entailed some extra trouble and the capillary tubes and arm-to-arm vaccination was simpler and deemed sufficiently satisfactory in those days.

I am, Sirs, yours faithfully,

HENRY KENWOOD,
Medical Officer of Health to the Parish of Stoke Newington.

April 6th, 1898.

"THE EYESIGHT OF SCHOOL-CHILDREN."

To the Editors of THE LANCET.

SIRS,—In an annotation in your issue of Feb. 19th last you remark on the attention of the medical profession and of the public to the defects of eyesight prevalent among school-children and you kindly refer to my own efforts in this direction. It may not be without interest to briefly mention what has been done in this city as a result of the lectures given by me from time to time to the elementary and other teachers. The last lecture was about twelve months ago and was then delivered at the request of the assistant teachers who it is pleasing to mention had become alive to the importance of the subject, and it is greatly due to the activity of Mr. M. Davenport, one of their number, that action has now been taken. After the delivery of this lecture the Chairman of the School Board was approached by the teachers and they found him and the other members of the board in full sympathy with their desire to benefit the children and the result was that the board schools were supplied with test charts with instructions and circulars. The test chart adopted is after Snellen's types and the instructions accompanying each chart are to the effect that if vision only equals $\frac{14}{18}$ the parents are to be informed that the child's sight is defective and if it does not reach to $\frac{14}{36}$ they are to be told that vision is seriously defective. It may be remarked that the standard of vision regarded as defective and needing medical aid is placed at a higher point than has often been deemed absolutely necessary. Mr. Priestley Smith held, for instance, that all cases who failed to read type equal to $\frac{6}{12}$ might be condemned and that this would practically reach such cases among school-children as needed attention. Mention is also made in the instructions issued to teachers with the test charts of the importance of: (*a*) the posture of the child at the desk; (*b*) the position in the class with regard to lighting and nearness to the blackboard; (*c*) the type in the reading books. Should examination with the types discover defective vision in one or both eyes the head teacher of the school is directed to forward a circular to the parent stating the fact and recommending that the child should have medical advice. A second circular is provided to be issued later if the first has not produced the desired effect. I am, however, informed that the response on the part of parents to the recommendations of the teachers has thus far been very general and satisfactory. One teacher tells me that out of 120 who were found defective in a large school at the first examination he was quickly able to find out that 57 had received medical aid. The head teachers were desired to test the eyesight of all children above the first standard and of all new children on admission. A further test is to be given at the end of six months in those instances where no steps have been taken to remedy the defect. The question of the eyesight of school-children has properly created a good deal of interest which is now bearing fruit. In other places some sort of system has doubtless by this time been adopted, and the plan now in use in Sheffield is merely mentioned as one that is likely to be of service in combating the deleterious influences of school life on eyesight.

I am, Sirs, yours faithfully,

SIMEON SNELL,
Ophthalmic Surgeon, Royal Infirmary, Sheffield.

"COLLAPSE FOLLOWING LAPAROTOMY."

To the Editors of THE LANCET.

SIRS,—In reference to your note I have injected brandy and strychnine with saline solution into a vein and know of several cases in which this was done. Two drachms of brandy with 3 minims of liquor strychninæ in a pint of saline solution do not injure the endothelium of a vein and are not sufficient to produce toxic symptoms. In a collapsed patient a hypodermic injection is absorbed either very slowly or not at all, until the circulation improves, when, if several hypodermics of strychnine have been given, the patient sometimes becomes convulsed. Next best to intravenous injection is the intramuscular followed by massage. It is illogical to give a hypodermic injection in the forearm of a pulseless patient.—I am, Sirs, yours faithfully,

C. HAMILTON WHITEFORD.

Sussex-terrace, Plymouth, April 10th, 1898.

To the Editors of THE LANCET.

SIRS,—I have read Mr. C. Hamilton Whiteford's letter on Collapse following Laparotomy and your footnote with regard to the intravenous injection of brandy and strychnine in THE LANCET of April 9th, 1898, and think that the following case may prove of interest to some of your readers

as showing that the intravenous injection of brandy in this case at least was followed by no injurious effects.

A child, aged seventeen months, was admitted into this hospital in February last suffering from tuberculous arthritis of the left knee-joint. The child was small and very badly nourished. Mr. Eve opened the joint and performed arthrectomy. After the operation the child was collapsed, the pulse being quite imperceptible and the surface cold and clammy. Brandy was injected into the rectum, but it partially returned and subsequently brandy, ether, and strychnine were given by hypodermic injection. I was called to see the child in about half an hour and found it still in the same condition, the pulse being quite imperceptible. I opened the right basilic vein and injected ½ pint of saline solution to which 3 oz. brandy were added. During the transfusion the pulse became perceptible and when it was completed was full and of good force and tension. The collapse never returned and the child recovered perfectly.

I am, Sirs, yours faithfully,

CHARLES BOLTON, B.Sc., M.D., B.S. Lond.,
Senior Resident Medical Officer.

Evelina Hospital for Sick Children, Southwark Bridge-road, S.E., April 11th, 1898.

THE RECENT INQUIRY AT THE BRISTOL CHILDREN'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I have read your notice about the friction at the Bristol Children's Hospital and in reply would beg you, in the interests of justice, to insert my few words of explanation. When I went to this hospital I found, as the Medical Directory shows and as all now acknowledge, that the qualifications of the staff were lower than that of any similar hospital of the size. I was pledged to stay a year at my post and having had much greater advantages and more previous practice than some of the staff I placed what I knew in the most brotherly way before some of them. This was received well for some time, but gradually a feeling arose that I was in a false position. I got some reforms and gradually, in self-defence, I was forced to look to myself. Leaving reform to the committee, some of whom had supported me, I tried to get credentials in order to get away with honour. Failing this, I sought to be justified by the committee with some minor post and at last, after a year's private agitation for some justification, finding the Medical Society did not care to touch the matter and finding the reforms still hung fire, I determined to carry out my idea of getting reform by the severe pressure of printer's ink.

Now although I have got the hospital practically remodelled, with a new out-patient staff, a new in-patient surgical staff, new matron, some new nurses, and new rules for future guidance, I am, in the interests of this and, I presume, all hospitals and of the discipline for house surgeons in general, temporarily sat upon. It is to be noted, however, that mine is an exceptional case. I do not wish to encourage criticism by house surgeons; but stress of misfortune put me into a post of house surgeon with a staff exceptionally below the usual English standard. Reform was necessary and reform is gained by my self-sacrifice. It is a matter of honour with me now to prevent my name being trampled in the mire, sorry as I am that I have seemed to attack others. It must be known, however, that I am on my defence against a charge of causing "friction," and the cases related were not at first given as "charges," but merely instances of "friction." The opposite side called them "maltreatment," &c., and some lawyers have said they must be so considered. If so, no proper chance of proof has yet been given, for the judges have invariably been chosen under the auspices of the hospital or its friends and I have not yet put all the evidence before any inquiry. The matter must therefore be held as still *sub judice*.

I am, Sirs, yours faithfully,

W. L. CHRISTIE.

Church House Children's Hospital, East-street, Bedminster, April 4th, 1898.

A MIDDLE-CLASS HOSPITAL FOR LONDON.

To the Editors of THE LANCET.

SIRS,—Permit me on behalf of the promoters of the proposed middle-class hospital for London, referred to in your condemnatory article in THE LANCET of April 2nd, to respectfully challenge the grounds of your opposition, which I gather from the article to be:—1. That the establishment of such an institution would add to the financial embarrassment of existing hospitals. 2. That we have enough hospitals already or as many as can be properly maintained. 3. That we have the Metropolitan Asylums Board hospitals free to all. 4. That the hospital, if founded, would not be self-supporting. 5. That the cases of middle-class patients who cannot be accommodated at home are comparatively rare and are met by the existing private nursing homes, where they can be received on "reasonable terms."

1. Regarding the first objection, we submit that the initial funds needed for starting a middle-class hospital (assuming it to be subsequently self-supporting) could not, in such a city as London, materially affect hospital charities in general; and, further, that as far as the middle classes are concerned, at all events, they would be quite justified in helping to provide a hospital suited to themselves if the need for such exists; and I may add that the building of a new hospital is not at present contemplated, it being believed that suitable premises can be secured at a moderate rental. 2 and 3. In reference to there being as many hospitals already as can be properly maintained and to the existence of the Metropolitan Asylums Board hospitals, we would point out that the present project is based on a carefully made calculation that the middle-class hospital would be self-supporting after its foundation and not any further burden on public charity, that although we have many hospitals we have none of this kind, and that the Asylums Board hospitals do not meet the peculiar requirements which the middle-class hospital would provide. 4. The question of a middle-class hospital being self-supporting, established for patients willing to pay a moderate residential fee and having, if desired, their own medical men, turns largely on the next point (5) the demand for such an institution. Here we beg most emphatically to deny the accuracy of your view that the cases are "comparatively rare" where the sick among the middle classes require the accommodation, nursing skill, medical supervision, and appliances of a "hospital," but without the dishonour of the pauper ward. This point we confidently leave to the experience of your readers in the practice of their profession. Your statement that the existing private nursing homes meet these cases on "reasonable terms" we must also take exception to. Whether an average charge of from four or five guineas per week upwards be reasonable terms to middle-class patients of limited and often much burdened incomes, is a question which the majority of such patients answer by submitting themselves to the perils and their families to the worry and discomfort of the sick room at home, through inability to meet the quite prohibitive charges of the ordinary private nursing homes, with their limited and often defective accommodation. So far as our investigations have gone, we have had ample confirmation of how sorely the need for the proposed hospital is felt by the middle classes. Hoping that a reconsideration of the subject may enable you to modify your views, and trusting you will find space for the insertion of this letter,

I am, Sirs, yours faithfully,

S. STRATFORD MALONE,
Secretary to Committee.

"A SYMPTOM FOLLOWING ANGINA PECTORIS."

To the Editors of THE LANCET.

SIRS,—With reference to the clinical note in your last issue by Dr. Worton of Redditch under the above heading, the vaso-motor symptoms noted as affecting the left middle finger are of interest as illustrating the surface phenomena connected with visceral disease. It also illustrates a point which clinicians have to bear in mind—namely, the avoidance of too unquestioning an acceptance of the views of experimental physiologists. The value of Dr. Worton's note consists in its showing that peripheral phenomena may avoid what are regarded as the most direct routes for radiation and select in the first instance territories only reached as a rule by secondary reflex. The vaso-motor fibres in the case in question run, of course, in the median nerve, which is the offspring of the first dorsal and eighth cervical segments so far as the heart is concerned. Physiologists, however, note with a mark of interrogation the cardiac outflow from the first and fourth dorsal segments

and derive it chiefly from the second and third. The frequency with which painful peripheral signs in angina reach the elbow by way of the cutaneous branches of the intercosto-humeral nerve, which arises from the second dorsal segment, lends some force to the above physiological conclusion, but the mode in which anginal reflexes cover an extensive nerve area when pain is severe renders it probable that physiological preconceptions may be too narrow for the explanation of some clinical facts.

Dr. Worton accounts for the occurrence of the phenomenon in his case upon the left side by the "much more extensive nervous connexions on this side through the brachial plexus with the cardiac nerve apparatus." I think he will agree with me on reflection that it was more probably due to the situation of the cardiac disease in the left heart. I presume this was so, although Dr. Worton does not expressly state so much. The nervous connexions of the right side of the heart are anatomically quite as extensive as on the left side, and in a rare case of disease of the pulmonary and tricuspid valves associated with angina pectoris which I published in the Transactions of the Pathological Society of London in 1876 the peripheral phenomena extended down the right arm to the tip of the right little finger, just as one so frequently observes them to take that course in the left arm when the causal disease is situated in the left side of the heart.

I am, Sirs, yours faithfully,

ALEXANDER MORISON, M.D. Edin.

Upper Berkeley-street, W., April 18th, 1898.

"THE MIDWIVES REGISTRATION BILL."

To the Editors of THE LANCET.

SIRS,—There is a statement in your leading article of March 12th that "their high rate of mortality has been guessed at and possibly exaggerated," thereby referring to untrained midwives, and I should like to do so more especially as Mr. Humphreys expresses regret that I still disbelieve in this high mortality. I beg therefore to submit that so far as any evidence can be produced on the score of high mortality there is strong all-round presumptive evidence that the mortality is little—taking all in all—if any at all affected. Certainly there are no statistics which will show the ratio of mortality between untrained midwives and registered practitioners and, moreover, as has been pointed out before, the mortality on the continent exceeds ours and the system of legislative control has shown marked signs of collapse and the continental public a strong tendency to revert to doctors. No doubt numerous witnesses with, I fear, preconceived ideas, but of whom I speak with marked respect, came before the Select Committee of the House of Commons and stated their general ideas on the question, but without chapter and verse, and the majority of these witnesses, if I recollect, had been accustomed to town practice, which affords no field whatever for observation in this matter. Some stated one thing and others something totally different and, as a consequence, the whole evidence resolved itself into one chaotic mass. The majority, however, were against midwives and as a consequence when a majority think one way and a minority think another the committee, having to arrive at some verdict, had no alternative but to report in favour of legislation. With regard to registration generally, if the principle is once acceded to the opponents of registration may take my cue for it that, barring one exception, it matters scarcely one brass farthing what is inside the Bill or another brass farthing what is outside of it, and the exception is this. Now Mr. Humphreys has distinctly stated on behalf of his party that the object of registration is to enable the public to distinguish between a trained midwife and one who is not trained. At the same time it is proposed to confer Parliamentary honours on thousands of Gamps, thus jumbling up the registry with the trained and the untrained. Surely this kind of coalescence cannot be tolerated. Now, Sirs, I ask if Mr. Humphreys and his party can conscientiously say that they are helping the public to distinguish the trained and the untrained by methods of this kind. Surely some distinguishing feature should be noted in the registry, say, for instance, "passed by examination" to those who have passed, which might enable the public to differentiate between the Gamps and the newly fledged.

I am, Sirs, yours faithfully,

Peckham, March 29th, 1898. CLEMENT H. SIBS.

"THE WALSALL MEDICAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—In your issue of April 9th you stated that you had received from a correspondent a copy of a letter which a member of the above society is said to have addressed to the secretaries of sundry friendly societies; you commented that the letter in question was not one which should have been written. At a meeting of the society held on April 15th it was resolved, "That the members of the Walsall Medical Society entirely deprecate such action on the part of any member." The society has good grounds for believing that on being appealed to by the Medical Defence Union, to whom a copy of the letter was also sent, the member in question has expressed his regret at having offended in the manner indicated.

I am, Sirs, yours faithfully,

J. P. NIXON,

April 18th, 1898. Honorary Secretary, Walsall Medical Society.

"UNQUALIFIED ASSISTANTS."

To the Editors of THE LANCET.

SIRS,—Dr. G. P. Hadley's suggestion for the institution of a special examination for men over forty years, unqualified yet with a "full curriculum," seems to me to be as totally unnecessary as it would be a retrogressive step. In the first place, what is a man with a "full curriculum"? I take this to mean "signed up" for all lectures, all hospital work, all examinations but the final passed; then why a special examination? There are many open to him, from—in point of expense—the Apothecaries' Hall, London, upwards. If it is a question of funds—and poverty is the general excuse of the unqualified—the special examination suggested hardly meets the case, as the fee would hardly be lowered; indeed, in case of special examinations it is usually considerably increased. Dr. Hadley urges that unless some such sort of examination is instituted these men will be driven into the ranks of the "unqualified and unregistered practitioners"! Indeed! Where are they, may I ask? What position do they occupy now? It *is* a grave scandal that so many practitioners should have been found, in face of the repeated warnings of the Council, to "cover" these unqualified men and so assist in perpetrating a fraud on the public, and on that portion of the public, too, which is least able to discriminate between the legitimate and illegitimate practitioner.

Sooner or later the unqualified and unregistered man will be dealt with, and though there may be delay, the law must be eventually altered to deal with these impostors as any other fraudulent class. To help the genuinely poverty-stricken man who is prevented from entering for his "final"—for which he *must be eligible*—for want of funds, let Dr. Hadley and the other *disinterested* practitioners neither seek to lower standards of examination nor to open a back door into a profession already filled to the overflowing with men who have spent their time, energy, and money in obtaining their qualifications, but let them put their hands in their pockets and subscribe and help to start a fund to enable the man "*sine* diploma but with full curriculum" to qualify. It need not be a large amount: there are very, very few unqualified men with a genuine "full curriculum" and there are very few unqualified assistants the admission of whom into the profession by such questionable means as suggested by Dr. Hadley would be any benefit to it, except perhaps to those large-minded practitioners, their employers, who would continue to "sweat" them.

I am, Sirs, yours faithfully,

April 19th, 1897. M.A. CAMB., M.A., M.B. DUBLIN.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A Special Sanitary Service.—Bacteriological Laboratories.—Plague Inoculation.

THE present seems to be a particularly suitable time for establishing a special sanitary service for India. The subject has been talked about for many years, but has been postponed from financial considerations. There is hardly

any question that a radical change in the sanitary administrations of Indian towns, both large and small, is one of the most urgent needs for reform. The native forms of municipal government are so entirely influenced by the personal interest of the members that anything like sanitary progress under the present *régime* is hardly to be expected. The few sanitary commissioners are practically officers without men and their powers are limited. In Madras there are district medical and sanitary officers but they are not specially qualified in sanitary science. It has been suggested that the medical men holding the public health diploma who have been recently sent out by the Secretary of State should be offered appointments of this character and should form the nucleus of such an organisation. There would be no difficulty in obtaining other officers from England to satisfy the requirements for the further development of such a service. In addition, it should be compulsory on all municipalities to appoint as health officers only those who hold a sanitary qualification. This certainly should be made to apply to all towns of 50,000 people. It might be objected that such an establishment would be interfering with the province of the Indian Medical Service, but if there were shown any real disposition to create such an administration this difficulty might easily be overcome. Either the public health officers might be placed in a special service or they might be incorporated *for special work* in the Indian Medical Service. What is of vital importance, should such an organisation be created, is that the officers should possess a sanitary qualification. At the present time the Indian Medical Service could provide but a few men adequately prepared to fill such offices, so that either time must be allowed for a new generation of men qualified in public health work to be developed or assistance of men from England who are not in the service must be requisitioned for the special purpose. As a matter of general administration it would probably be better to create a special service or, if under the control of the heads of the Indian Medical Department, with an entirely distinct organisation. It is high time also that native medical men should have inducements offered to them to take up sanitary qualifications. The smattering of instruction in hygiene which the universities and colleges at present give is totally inadequate. Regular examinations and degrees in public health might readily be established. Another most urgent want is the provision of a thoroughly well-equipped bacteriological laboratory properly officered for each presidency. India offers so many diseases in man and animals which require further scientific investigation that the opportunities at present lost are much to be deplored.

The Government of Bombay have at last conceded that the Plague Committee should be instructed to exempt from segregation or detention persons who can produce satisfactory evidence of having been inoculated within the previous four months. They stipulate, however, that the inoculation shall have been performed by specially selected officers and that the premises, clothing, and effects of the inoculated persons shall be properly disinfected. These conditions are necessary to safeguard the possibilities of conveying contagion, but of course involve considerable trouble and hamper business movements very greatly. It is, however, a concession of considerable magnitude. It remains to be seen whether the Plague Committee will give facilities for inoculation beyond those offered by the municipality. If these inducements had been offered earlier it would have led thousands to willingly offer themselves for inoculation. The delay has been disastrous, if not to the lives of the people, to the trade of the city. If inoculation with Haffkine's prophylactic fluid can be permitted now to replace the necessity for detention and quarantine it might equally well have been allowed four months ago.

The past week has shown a marked decline in the mortality from plague; while there has been some improvement in the city for some two or three weeks past; the suburbs continue to be seriously affected. Now, however, there are signs of abatement everywhere. Judging from past experience the decline will regularly continue and we shall probably see an almost complete subsidence in the course of six or eight weeks. The type of the disease is also not so severe. The system of segregation has been still further relaxed and the granting of passes to traders is more freely given. House-to-house visitation has been practically abolished and very few "contacts" are now removed. In short, all the measures of the Plague Committee hitherto adopted with such stringency have been practically suspended and yet there is not the slightest evidence of further spread of the disease. This clearly shows either that severe sanitary measures are not required for plague or that when once an epidemic shows signs of declining the various rules of inspection, segregation, detention, and disinfection can be done away with. The disease seems to take its own particular course whatever may be done, although doubtless sanitary measures have an influence on the extent or the severity of the outbreak. Relapsing fever seems also to be dying out.

April 2nd.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

"*The Dangers of Medical Life.*"

WHAT was aptly described as above by the presiding magistrate at Aston Police-court on April 15th is an illustration of the difficulties which sometimes beset the medical practitioner in the discharge of his duties. Mr. Parry, a surgeon, was brought to the court on a warrant charged with committing a criminal assault on a Mrs. Mathews. The solicitor who had been instructed to prosecute said that since the case was put into his hands he had examined the witnesses for the prosecution and in his judgment the evidence did not support the charge. The statement of prosecutrix was not corroborated in important points. Mr. Vincent Jones, to whom Mr. Parry acted as assistant, was called and he stated that he found the prosecutrix suffering from hysteria and that Mr. Parry had only done what was quite right in enforcing the administration of a soothing draught. The Bench decided that Mr. Parry was entirely and completely exonerated, stating that such cases frequently occurred and expressing their sympathy with any gentleman subjected to such a charge as this. A favourable ending to an unfounded charge of so serious a nature hardly compensates for the perils the medical man is exposed to in dealing with a certain class of patients, but it affords an example of the annoyance and risks which constitute one of "the dangers of medical life."

Death under Chloroform.

A death under chloroform happened at the Guest Hospital, Dudley, on April 14th. The patient was a young woman, aged twenty-four years, suffering from a deep-rooted abscess of the right breast. About five drachms of chloroform were administered by Mr. Tuxford, the house surgeon, in the presence of Dr. A. S. Underhill. The deceased struggled violently until she became insensible. Directly the operation was concluded the breathing ceased. Dr. Higgs, who made the post-mortem examination, stated that the brain was slightly congested, but that all the organs were healthy; in his opinion death was due to paralysis of the muscles of respiration. A verdict of "Death from misadventure" was returned by the jury at the inquest held on April 18th.

April 19th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Changes at the Liverpool Hospitals.

THE number of vacancies on the senior staffs of the Liverpool hospitals has been exceptionally large during the last three months. To begin with there occurred the vacancies at the Royal Infirmary, at the Royal Southern Hospital, and at the Ladies' Charity and Lying-in Hospital — all owing to resignations through lapse of time. These posts have been filled up as recorded in THE LANCET. The vacancy on the surgical staff of the Stanley Hospital caused by the appointment of Mr. G. P. Newbolt to the Royal Southern Hospital was filled up on the 12th inst. by the appointment of Mr. Douglas Crawford, who had been for three years assistant surgeon to the hospital. At the present time there are vacancies on the staffs of the Women's Hospital and the Ladies' Charity and Lying-in Hospital due to the appointment of Dr. T. B. Grimsdale to the Royal Infirmary, the regulations of the Royal Infirmary not allowing of the retention of similar posts at other Liverpool hospitals by members of its staff.

The Proposed Small-pox Hospital at Fazakerley.

Mr. W. W. E. Fletcher, inspector of the Local Government Board, held an inquiry at the Municipal Offices, Liverpool, on the 19th inst. in reference to the application by the Liverpool Corporation for powers to borrow £38,000 for the purchase of a site for a small-pox hospital and convalescent home at Fazakerley. The application was opposed by owners of estates in the vicinity. The town clerk of Liverpool in supporting the application detailed at length the steps which the corporation had taken during the last fourteen years to provide accommodation for infectious diseases, which had proved most beneficial in restricting infection and in improving the general health of the city. Although the Registrar-General's return stated that the death-rate of Liverpool was very high, yet the population upon which those returns were based was much under-estimated, as the actual population of the city was 50,000 in excess of the official figures. The official return put down the population at 643,000, whereas in point of fact it ought to have been 690,000. The corporation found themselves bound to provide for the actual number. Under existing circumstances the corporation had to ask poor-law authorities to receive infectious cases in workhouse hospitals, where there was no doubt they were a source of danger. At present there were at the disposal of the corporation 540 beds for the treatment of infectious diseases, but 260 of these beds were in wooden buildings of a temporary character. Another point emphasised by the town clerk was that there was no hospital for the treatment of small-pox at the north end of the city, which was most densely populated. The corporation did not admit that there was danger to the general public from institutions of this character provided the regulations of the Local Government Board were observed. The proposed site was large enough to enable the hospitals committee to have the required 400 yards of space between the small-pox and convalescent hospitals which they proposed to build and also to allow of ample space between these buildings and whatever houses might be erected on land adjoining. There was some argument between the opposing parties in reference to the estate having a clay subsoil which, it was stated, would render it unfit for hospital purposes, and also with regard to the fact that owing to the overflow of the Fazakerley brook the property was liable to periodical flooding. Dr. Hope supported the application of the corporation and adversely commented upon the adoption of floating hospitals on the Mersey. He also said that he had never known a case of infection traced to an ambulance carriage in progress through the streets. The great recommendation of the proposed site consisted in the fact of its nearness to the densely populated parts of the city.

The West Derby Guardians on the Treatment of Pauper Imbeciles and Epileptics and the Midwives Bill.

The West Derby Board of Guardians are about to enter into an agreement with the select vestry of the parish of Liverpool and the Ormskirk Union for the classification and accommodation of epileptic, imbecile, and weak-minded children. The West Derby board are to provide accommodation for 110 juvenile epileptics, the select vestry are to find accommodation for 170 imbeciles, and the Ormskirk guardians are to provide for 60 weak-minded children. The new movement is in the direction of classification of these diseases, which require special treatment. The West Derby board of guardians have also resolved by a majority of 18 votes to 9 to petition Parliament in favour of the Bill for the Compulsory Registration of Midwives. Two prominent medical members of the board opposed the resolution on the ground that it was full of dangers which, in the interests of the poor, it was desirable should be avoided.

The Dangers of False Teeth.

An inquest was recently held by the city coroner touching the death of a grocer's assistant aged thirty years. The deceased wore false teeth attached to a vulcanite suction-plate and fastened to his natural teeth by wires. He was in the habit of sleeping with the false teeth in his mouth. On the morning of March 19th the deceased unfortunately swallowed the false teeth during sleep. He was taken to the Royal Southern Hospital when the teeth were felt to be impacted at the junction of the pharynx with the œsophagus on the left side of the larynx. As it was found impossible to remove the teeth by manipulation they were eventually withdrawn through an artificial aperture made in the neck. However, the unfortunate man succumbed a week later, septicæmia having supervened.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Glasgow Fever and Small-pox Hospitals.

THE report of the City of Glasgow Fever and Small-pox Hospitals for the year ending May 31st, 1897, has just been issued. The greater part of it is by Dr. Alexander Johnston, physician-superintendent of the fever hospitals, the few pages devoted to the small-pox hospital being by Dr. R. St Thomson. The general statistical summary of the patients is as follows: remaining in hospitals June 1st, 1896, 607; admitted during 1896–97, 4861; cured, relieved, and died, 4997; remaining in hospitals May 31st, 1897, 471. The total number of deaths was 497, of which 91 occurred within forty-eight hours of admission, and the general mortality calculated on completed cases was 10·2 per cent. The daily average number of patients was 627, of nurses and servants 319, and of officers 14. The average residence of each patient was between forty-one and forty-two days; the total ordinary expenditure was £34,224; the average daily cost per patient was 2*s.* 11·9*d.*; and the average cost of treatment per patient was £6 5*s.* 2½*d.* The 4861 cases admitted were classified as follows: scarlet fever, 1956 (with 89 deaths); diphtheria, 180 (with 38 deaths); enteric fever, 545 (with 106 deaths); typhus fever, 13 (with 5 deaths); small-pox, 2 (with 1 death); chicken-pox, 29 (with 1 death); measles, 1442 (with 164 deaths); whooping-cough, 348 (with 56 deaths); erysipelas, 53 (with 4 deaths); puerperal fever, 26 (with 9 deaths); epidemic roseola, 13 (with no death); the admissions also included 108 nursing mothers and 143 cases of non-infectious disease, among which there were 41 patients suffering from pneumonia. The average periods of residence for the various classes of disease were as follows: scarlet fever, fifty-eight days; enteric fever, fifty-five days; whooping-cough, fifty-three days; typhus fever, twenty-eight days; measles, twenty-nine days; and small-pox, thirty-one days. The classification of the admissions according to age was: under ten years, 3382 or 69·5 per cent.; between ten and twenty-five years, 1132, or 23·2 per cent.; and over twenty-five years, 347, or 7·1 per cent. The scarlet fever mortality was 4·5 per cent., being the lowest in the history of these hospitals. Anti-streptococcic serum was tried in scarlet fever, but nothing to show that it was of great value was observed. Laparotomy was performed in two cases of intestinal perforation occurring in enteric fever, but without averting a fatal result. The clinical classes were attended by 110 male and 15 female students. A paper on "The Administrative Treatment of Undefined Cases certified as Scarlet Fever," by Dr. Frederick Dittmar and Dr. John Brownlee, assistant medical officers at one of the fever hospitals, was published in THE LANCET of April 3rd, 1897.

April 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Meath Hospital, Dublin.

THE annual meeting of the Governors of the Meath Hospital and County Dublin Infirmary was held on April 18th, under the presidency of Sir Philip Smyly. The secretary, Mr. Francis Primrose, read the annual report, which showed that the hospital had been maintained as regards all its departments in a most efficient condition during the past year and that the convalescent home at Bray in connexion with the hospital had continued to confer much benefit on the patients sent there during the last twelve months. Dr. J. W. Moore moved a vote of thanks to the County Grand Jury and remarked that this would be the last occasion on which they would have an opportunity of thanking the Grand Jury, to whom they were greatly indebted for their interest in the institution and for their substantial grants to its funds. He stated that he

had every expectation that the members of the new county council would recognise their interest in also supporting an institution which had been for the last 150 years, the county infirmary of Dublin. Sir William Stokes moved: "That owing to the necessary provision for a new operating theatre, an additional accident ward, and a new laundry the Governors appealed strongly to the public for aid." He mentioned that these essential improvements, which were almost completed, had strongly taxed the resources of the hospital. It was satisfactory for them to know, however, that few operating theatres in the country or on the continent would be superior to their new operation theatre when completed.

The Local Government Bill and the Asylums.

A convention of governors representing all the asylums in Ireland is to be held in Dublin at the end of the present month to consider certain proposals arising out of the Local Government Bill. Many people think it would be much better for the country if the Government took into their own hands the management of the Irish asylums and the Derry Asylum Board have already passed a resolution to this effect.

Death of the Countess of Shaftesbury.

The public of Belfast heard with feelings of the utmost sorrow of the death of the Countess of Shaftesbury, which took place at Rome on April 14th, in her sixty-first year, from pneumonia secondary to influenza. One of her ancestors, Sir Arthur Chichester, Lord Deputy of Ireland in his day, has been called the founder of the city of Belfast. The Countess of Shaftesbury was the daughter of the third Marquis of Donegall and on his death in 1883 the late countess came into possession of the greater part of the extensive estates of the Donegall family in Antrim and Down, including valuable property in Belfast. She married Lord Ashley (son of the great Lord Shaftesbury), who succeeded his father, but died soon afterwards. The Countess of Shaftesbury possessed a beautiful residence in the vicinity of Belfast and she took the deepest interest in all charitable and philanthropic objects of the city. She was a special friend of the Society for Providing Nurses for the Sick Poor and she had a great deal to do with the Nurses' Home, often presiding at the annual meetings of that institution. She was also a true friend to the Royal Hospital and made a grant of the site on which it is built to the board of management, with right to sell it when the hospital was ready to be removed to its new site. This gift was estimated as being worth £10,000. The ground on which the hospital stands was held on a terminable lease, which was reaching the time of expiration when the Countess, with the consent of her son who had just come of age, gave it to the hospital authorities.

Birth of Quadruplets.

A woman named M'Grath, residing at Tallow, co. Waterford, gave birth to four daughters on the 28th of last month. Application was made for the Queen's bounty and Sir Arthur Bigge, keeper of Her Majesty's privy purse, forwarded a cheque for £4 with a request to be informed as to the health of Mrs. M'Grath's infant daughters.

Influenza in the Limerick Lunatic Asylum.

At the last meeting of the board of governors Dr. O'Neill, resident medical superintendent of the Limerick Asylum, reported that during the month there had been a considerable amount of sickness on both sides of the house and that nearly every bed in the hospital had been occupied, the patients suffering principally from influenza and pneumonia.

Cork South Infirmary and County Hospital.

At the last meeting of the board of trustees of the above institution Lieutenant-Colonel Donegan informed the trustees that the Countess Murphy had authorised him to state that she would be prepared to give £2000 for the building of a chapel on the grounds of the infirmary for the use of the Roman Catholic patients. Colonel Donegan, in moving that a committee be appointed to select a site, mentioned that allowing patients to go into the city to attend at their respective places of worship sometimes interfered with the discipline of the hospital and pointed out that it would be much more desirable that facilities should be afforded to them for attending to their religious duties within the precincts of the hospital. The trustees expressed their appreciation of Countess Murphy's generous proposal and a committee was appointed in accordance with Colonel Donegan's proposition.

April 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Maternal Thyroid Treatment of Goitre in the Newly Born.

AT the meeting of the Academy of Medicine, held on April 12th, M. Mosse read an account of a woman, aged twenty-nine years, who was the subject of a goitre accompanied with feeble-mindedness, but without symptoms of myxœdema. Her general health was good. Her child, who was three months old and breast fed, had a large bilobed goitre, was very puny and sickly, but had no signs of myxœdema. The mother was put upon thyroid treatment and took daily a quantity of thyroid extract corresponding to 1½ grammes of thyroid gland. At the expiration of one and a half months the mother's goitre had diminished in size, but a still more marked result was obvious in the child, whose general health was excellent. After the lapse of a slightly shorter period of treatment the goitre in the infant had completely disappeared and it was making good progress, while the goitre in the mother continued to decrease. This is the first recorded case of the influence of thyroid treatment being transmitted from mother to child in the milk.

The Degree of Doctor in the University of Paris.

M. Greard, the President of the University Council, is just about to publish the regulations relative to the degree of Doctor in the University of Paris. These rules will come into force at the commencement of the scholastic year. The following are the principal features, applying more particularly to students in medicine, pharmacy and science. Those who wish to proceed to the doctorate must inscribe their names in a special register at the secretarial offices of the Faculty or school of the university in which they wish to pursue their studies. For the purposes of this enrolling of their names they must give in their diplomas, certificates of study or of having obtained scientific distinctions, and will be bound to fulfil the course laid down by the present regulations and to undergo a public test. They will also be bound by the disciplinary regulations of the university. At the Faculty of Sciences claimants for the degree must produce two certificates in the superior class of studies, which include differential and integral calculus, mechanics, astronomy, the higher analysis, the higher geometry, celestialmechanics, mathematical physics, mechanical and experimental physics, general physics, general chemistry, mineralogy, biological chemistry, zoology, botany, geology, general physiology, and physical geography. The Faculty reserves to itself the right of accepting equivalent certificates for the above mentioned in the case of foreigners. The term of necessary study is one year and the test consists in the sustaining of a thesis containing the candidate's personal researches and in answering questions put by the Faculty. At the higher school of pharmacy candidates must if they be Frenchmen produce the diploma of a pharmacist of the first class or if they are foreigners submit two certificates—firstly, of having studied pharmaceutical chemistry and toxicology, and secondly, of having studied galenical pharmacy and materia medica. The school reserves to itself the right of deciding what shall be received as equivalent for these studies. The term of necessary study is one year at least. The test consists in the sustaining of a thesis containing personal researches. The diploma of Doctor of the University of Paris is granted to foreign students who have obtained leave to study and undergo examinations at the Faculty of Medicine of Paris and have been allowed to dispense with the degree of Bachelor. It is as well to recall the fact that by the 15th article of the decree of July 21st, 1897, the new title confers none of the rights and privileges belonging to degrees by law and can in no case be considered as equivalent to a degree. Henceforward, therefore, there can be no manner of doubt as to the position of foreign students in the medical school.

Legislation on the Practice of Pharmacy.

The Senate has just discussed the Bill already accepted by

the Chamber with reference to the practice of medicine and pharmacy. For the future the School of Pharmacy will not be allowed to accept as new students those known as pharmacists of the second class, a grade which will soon die out. In France pharmacists of the second class differ from others in this particular in that they need not have obtained the university degree of Bachelor of Arts and Sciences before commencing their studies in the School of Pharmacy. A certificate of merely elementary study is enough. In addition, having once passed, after a course of examination almost identical with that enjoined upon other pharmacists, they were prohibited from exercising their art in all the departments of France except one and could not change their residence without undergoing a new examination. They held the same relation to a pharmacist of the first class as a sanitary officer does to a doctor of medicine.

April 20th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Disinfection of Dwellings.

AT a recent meeting of the Berlin Medical Society a paper on a new method of disinfecting dwellings was read by Dr. Schlossmann, who said that the vapour of formaldehyde used for this purpose according to the directions of M. Trélat of Paris and Dr. Aronsohn of Berlin is very liable to polymerisation, whereby it is converted into a substance of very little antiseptic value. When this occurs only the superficial bacteria are destroyed, whilst those between the planks of the floor or in the interior of feather-beds, clothing, &c., are not in the least affected. Dr. Schlossmann has, however, succeeded in avoiding polymerisation by evaporating the formaldehyde along with a mixture of water and glycerine, the latter of which combines with the formaldehyde. Clothes impregnated with purulent matter were thoroughly disinfected by this method in three hours at most without any injury to either the material or the colour. The disagreeable smell may be destroyed by ammonia.

The Philanthropist's Requital.

Dr. Leichtentritt, a medical practitioner of Berlin, has had a very strange and disagreeable personal experience, the details of which he has published in the *Aerztliche Sachverständigen-Zeitung* for the benefit of his professional brethren who may at any time be placed in similar circumstances. Dr. Leichtentritt one evening when on his way home and near his residence was asked by a policeman to see a woman who was giving birth to a child in a water-closet. He did so and found that the woman had just been delivered of a girl, the placenta being still in the uterus. A crowd of women was, of course, present to watch the proceedings and to give advice to the patient. The surroundings not being the most suitable for obstetrical manipulations Dr. Leichtentritt only tied the umbilical cord and ordered that the woman, whose name and address he did not ask for, should be conveyed by the policeman to the nearest hospital for the removal of the placenta. He then went away, feeling inwardly content with the charitable act which he had performed under such strange conditions. Some weeks afterwards the woman called on him to ask whether he had notified the birth of the child to the registrar. She told him that she wished the child to be baptized and according to law it was necessary for the clergyman to see the certificate of the registration of birth. Dr. Leichtentritt said that he had not notified the birth and explained to the woman that it was the duty of the hospital officials to do so. Not long afterwards he was officially summoned before the registrar, who drew up a long report of the case, and his troubles were supposed to be at an end, but to his great disappointment he received an order from a magistrate to pay a fine of 1 mark (1*s.*) and 1 mark 40 pfennigs (1*s.* 5*d*) costs for infringement of the registration laws. Dr. Leichtentritt refused to pay, not feeling that he had committed any offence, and rightly believing that he did not deserve to be fined for help freely given to a poor woman. Legal proceedings were taken against him, but judgment was given in his favour on the singular ground that he had not been "present" at the delivery as the child was already born when he arrived on the scene. The law is to the effect that medical men or midwives or other people "present" at the birth of a child are bound to notify the birth to the registrar, but it was not applicable to the present case. In future Dr. Leichtentritt and some other medical men will probably be less ready to respond to appeals for their assistance.

April 18th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The De Renzi and Pane "Siero Anti-pneumonico."

THE series of clinical trials of this serum, elaborated by Professor De Renzi and Professor Pane, both of them distinguished members of the Neapolitan Medical School, is still in progress and the results hitherto reported are certainly gratifying. From Dr. Ughetti, ordinary professor of pathology in the University of Catania, and from Dr. Cantieri, director of the "clinica medica" at Siena, highly favourable opinions as to its efficacy have come, while Professor Massolongo, head of the Civil Hospital at Verona, concludes a careful and minutely detailed report as follows: "My impression as to the 'siero anti-pneumonico' is this, that it is more efficacious than any other agent. These first experiments of mine convince me that from the 'De Renzi and Pane serum' we can obtain a clearly defined action on the pneumonia process which it influences directly." Nine other clinicians whose names are before me have put a similar experience on record and confirm the results that have been communicated during the last four months to the Istituto Siero-terapico at Naples, where the serum is in constant preparation to meet a corresponding demand. In this department of therapeutics Italian medicine has assuredly struck out a track prolific of good.

"In this So-called Nineteenth Century!"

At Castelvenere, near Beneventum, in the Samnite country, a peasant woman has seen a vision of the Madonna who told her that near a neighbouring cemetery there would be found, by digging deep enough, an image of Our Lady of the Seven Sorrows ("Vergine dei Sette Dolori") which claimed the worship of the faithful. The impression produced by this declaration was profound; digging commenced and 60 ft. below the spot indicated was discovered an arched vault, in the recess of which was found the expected image (a picture) of the Madonna. The countryside has sent its thousands to pay their votive offerings to the revealed Virgin and already miraculous "cures" are announced—a blind man has recovered his sight, another man has been "cured" of cancer in the right hand—only from drinking the water that gushed out after the excavations and still flows abundantly. Of the pilgrims some have travelled a journey of fourteen hours. Indeed, we have all the makings of a "Neapolitan Lourdes" within measurable distance of one of Italy's greatest clinical schools. The "image," however, turns out to be "di data freschissima" (of most recent date) and the "cures" of lame, deformed, and blind votaries to be the old wives' fables of "promoters" interested in "running" a miraculous health-giving water. The prefect has forbidden further excavations and the bishop of the diocese has ordered the parish priests to withhold their countenance from the improvised shrine. That the incidents already described should have attracted thousands of the faithful to the spot remains the one significant feature of the whole affair—a sad commentary on the superstition and debasement of the Neapolitan peasantry.

Dangerous Adulterations.

Italy has seldom been so full of the travelling public as at present—hotels and *pensions* "regurgitanti" (to use her own graphic expression) with visitors, mostly of the English-speaking race. Laudably concerned for the sanitary interests of these "paying guests" she is redoubling her vigilance over the food-supply and the beverages, natural and artificial, tracking out the adulterator wherever she finds him, impounding his deleterious wares and inflicting heavy punishment ranging from fines to incarceration more or less "exemplary." For instance, in the Alta

Italia a well-known Brescian firm received a visit the other day from the Ufficio Sanitario of Milan and was found to have on its premises, for supply to the baking fraternity, large quantities of flour adulterated with "caolina"—that is, the double silicate of alum and potash, a substance employed in porcelain manufactories and very pernicious to health. Following up its search the Ufficio Sanitario discovered in several baking-houses of Brescia another quality of "flour" furnished by the same firm and containing from 0·85 to 4·0 per cent. of sulphate of barium, a powder not actually poisonous like the "caolina" but very heavy and hurtful to the consumer's stomach. Convicted of this serious contravention of the sanitary law the head of the firm in question was put under arrest, though afterwards let out by finding security for 3000 lire (£120). Again, in Southern Italy the Neapolitan "assessore d'igiene," Professor Vincenzo Gauthier, has quite recently come upon a new adulteration of olive oil whereby that commodity, so universally employed in Italian cooking, is charged with an impure ingredient called "oëlina"—very injurious to the digestive apparatus. He made a vigorous search of the various oil depôts in the city and neighbourhood and has, I see, brought several dealers to justice, impounding within the last day or two as many as 200 "quintali" (hundredweights) of adulterated oil. The prevalence of this nefarious "industry" which under the pressure of heavy fiscal impositions is taking new and extensive developments, is, as I have shown, counteracted by increased vigilance on the part of the Sanitary Office and the fact is *pro tanto* reassuring. But I may mention for the comfort of English-speaking compatriots that the larger and better-frequented hotels in the chief cities are almost invariably supplied with food and beverages alike sound and above suspicion and that it is only in houses described in the guide-books as "thoroughly Italian"—that is, third or fourth-rate or lying outside the beaten tract of the tourist world—that there is danger from adulterated articles. In these the visitor must be on his guard, otherwise he may find the "Chianti" so charged with alum (to simulate the pleasant "prickly" after taste of that typical wine) and the bread so impregnated with the same astringent as seriously to derange his digestion and to make his "pleasure trip" somewhat of a "chastened joy."

The General Practitioner in Italy.

The general practitioner's life, especially in the remoter communes, is not a bed of roses. He is, for one thing, the victim of taxation more oppressive than in any other country—taxation which credits him with gains he never earns and assesses him accordingly. Even the "medico-condotto" (practitioner pensioned by the commune) is apt to pay imposts in excess of his fixed salary and to feel the heavy hand of the fiscal agent at unexpected turns. Hear this case of genuine hardship that has just been communicated to me: "There are two of us in my commune inscribed as possessors of bicycles and compelled to pay the tax on the same. The office of the controller of weights and measures at which we must present ourselves and our bicycles for verification is at Grosseto, 60 kilometres (some forty miles) distant. There is no railway to it, but a provincial road the reverse of smooth. Well, we are summoned to appear at Grosseto at the said office by the 23rd inst. to have our machines stamped and to pay the tax. Besides the fatigue of it the journey will cost us 20 fr. apiece (some 15*s.*) for bed and board during our two days' coming and going; so my companion, rather than incur this loss in time and money, is ready to forego his bicycle. I, too, would gladly do the same were it not that I cannot overtake my professional rounds without that means of 'vicarious progression.' And so I am obliged to throw 20 fr. away, to cover eighty miles coming and going on a badly metalled road, to hire a substitute to take over my practice for two days, and all because I must in person pay a tax of 10 fr. at Grosseto!" The "medico-condotto" proposed other means of satisfying the law—getting the syndic to pay the tax for him and the controller of weights and measures to "verify" his machine on his next visit to the owner's commune; but all in vain. Next year the same hardship must be undergone and the year after that—*ad infinitum!* "Certainly," he concludes, "His Excellency the Finance Minister when he made the law must have thought that bicycles were only vehicles of pleasure for 'peacocking about' in the parks of Rome."

April 18th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Severe Headache relieved by Trephining.

THE following interesting case was brought before the Imperial Society of Medicine. A man, aged thirty years, applied to Dr. Djemil Pacha five months ago for the relief of severe excruciating pain on the right side of his head, most severe about the parietal region. The patient had recourse to all sorts of scientific and non-scientific methods to allay the pain, but all in vain. Drugs of every description were tried, yet the cephalalgia was so severe that the poor fellow had become quite melancholic and desperate and life seemed to him not worth living under those circumstances. Dr. Djemil Pacha proposed to open the cranium at the point where the pain was most acute. The patient was put under an anæsthetic and the skull was trephined, a portion of about the size of a shilling piece being removed. There was absolutely nothing abnormal to be seen on the meninges or the brain. Some punctures were also made with a fine needle in the hope of discovering a cause for the complaint. The operator thought he had done his part of the work, though with no apparent result. As the man came round from his unconscious state the first thing he said was, "How comfortable I am now." The operation was evidently a success, as it had quite relieved the man of his headache. The man has not had any headache, not the trace of it, ever since the operation. The members of the society saw the patient for themselves and were quite satisfied about the facts of the case. No explanation could be given for the cessation or disappearance of the headache. Dr. Djemil Pacha himself confessed his surprise at the result, but he thought the case might be ascribed to the effect of the air or the light which no doubt had access to the exposed portion of the brain.

Cattle Disease.

Disease amongst cattle has lately appeared in the farms and villages near Constantinople. Dr. Nicolle, the French director of the bacteriological laboratories, is reported to have discovered a special remedy for the disease. A medical commission has now been appointed to make experiments with the new remedy. The commission is composed of Dr. Vitalis, assistant inspector of the Superior Council of Health, and Dr. Zoéros Pacha, director of the Pasteur Institute in this town. The Minister of Finance is to give all the necessary help and facility for the carrying out of the experiments and also for assisting Dr. Nicolle in his study of the bovine disease.

April 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Prince Alfred Hospital, Sydney.

THE annual meeting of the governors and subscribers to the Prince Alfred Hospital was held on Feb. 24th. His Excellency the Governor presided. The statement of accounts showed that the receipts for the financial year, including a credit balance of £911 12*s.* 10*d.*, had been £17,280 16*s.* 2*d.* and the expenditure £17,597 12*s.* 8*d.* The year had been remarkable for the number of additional expenses. There was one item in the expenditure of £1531 8*s.* 6*d.*, almost the whole of which was attributable to the rebuilding of the operating theatre. The cost of chemicals and of provisions had also been exceptionally high. The annual report stated that the number of patients admitted during the year was 3254, which, added to a total of 199 remaining in hospital at the commencement of the year, brought the number of patients treated during 1897 up to 3453. Out of 3254 patients admitted during the year 976 had contributed more or less to their support while in hospital. The total amount contributed by patients had been £2401 0*s.* 8*d.* Early in the year the operating theatre had been reopened after an entire renovation rendered necessary to bring its arrangements and equipment up to date. In all respects the directors were glad to learn that the new theatre had been a great success. In the carrying out of this

undertaking, as of so many others, the hospital owed everything to the constant personal and detailed supervision of the late honorary secretary, Sir Alfred Roberts. In October of last year a letter had been received from Sir Alfred Roberts resigning his position as honorary secretary of the institution on the ground of impairment of health. The directors had by resolution expressed their deep sense of the signal services rendered to the hospital by Sir Alfred Roberts during the thirty years that he had been connected with it. The report expressed great appreciation of the work of the medical superintendent (Dr. Sawkins), of the honorary medical and surgical staff, of the matron, and of the nurses of the institution.

Resident Medical Officers and Fees for Inquests.

The Crown Law Department of Victoria has recently refused to pay fees for making post-mortem examinations for the coroner to the resident medical officers at the Alfred and Children's Hospitals, Melbourne, on the ground that the Act states that paid officers of public institutions are not entitled to such payments. The medical officers dispute that the hospitals in question are public institutions within the meaning of the Act as they are supported partly by public contributions, and they have recently drawn public attention to the dispute by failing to attend at inquests when required on two occasions, stating that they had not been regularly subpœnaed. The coroner states that their proper course is to sue the Crown Law Department for the fees.

March 7th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The Auckland Skin-grafting Case.

THE case of Baker *v.* Purchas, recently tried at the Supreme Court, Auckland, before Mr. Justice Connolly and a special jury, is probably unique and presents some very interesting features from a medico-legal point of view. The plaintiff, Miss Baker, a music and art teacher, sought to recover damages from Dr. A. C. Purchas, a well-known Auckland surgeon, for personal injuries resulting from the operation of skin-grafting. In the month of May, 1897, a Miss Eva Holdsworth was an inmate of the Auckland Hospital suffering from extensive burns. It was decided to perform the operation of skin-grafting by the Thiersch method and Miss Baker was one of three persons who consented to supply the skin needed for the purpose. Miss Baker in her statement of claim alleges that she only consented to have a small portion of skin removed, that 52 square inches were removed, that the operation of removing such skin was not to cause her detention in the Hospital but that she was detained there eleven days, that she was placed under chloroform, that she suffered for a long time "grievous pain and agony," and that her body had been permanently and largely disfigured. She also states that the nature and extent of the operation was not explained to her, that there was wanton excess of any licence or authority given by her, and she claimed £500 damages. It will be seen that the statement of claim practically contained three grounds: (1) neglect of duty in not informing the plaintiff of the nature of the operation; (2) deception as to the amount of skin to be removed; and (3) bad surgery. The trial lasted four days and a large number of professional and other witnesses were examined. As the trial proceeded the second and third grounds of complaint were abandoned by counsel for the plaintiff, it being clearly proved that no deception had been practised and also that the operation had been skilfully performed. The question for the jury to decide therefore was, did Dr. Purchas neglect his duty by not informing the plaintiff of the nature, extent, &c., of the operation? Dr. Lindsay, Dr. McKellar, Dr. King, and Dr. Haines, who were called for the plaintiff, were all of opinion that the nature and extent of the operation should have been explained to the plaintiff. Dr. Scott, who was also called for the plaintiff, stated that he had never performed a similar operation and could not say whether he would have first taken steps to ascertain whether the patient was aware of the nature of the operation or not. Dr. Purchas admitted in cross-examination that he had not explained fully to the plaintiff the extent of skin which he might find necessary to remove, but that she was aware of the nature of the operation. He most certainly considered that he had *carte blanche* to take as much skin as he required to complete the operation; he continued taking skin from her until he had completed the operation. Mr. Marsack, who was called by the defendant, "most certainly thought that an explanation was due to a person before an operation was performed." Mr. Justice Connolly in his summing up commented very severely on the evidence given by the plaintiff on her own behalf and stated that the jury must discount her evidence to a considerable extent. He read the medical evidence without comment, pointing out that the charge of want of medical skill was disproved and had been abandoned. He left it to the jury to decide whether there had been an omission of duty in not explaining the nature of the operation and whether the skin taken was in excess of the licence given by the plaintiff to the defendant. His honour's summing up was strongly in favour of the defence. The jury, after considering their verdict for about three-quarters of an hour, returned a verdict for the defendant unanimously. Dr. Purchas is to be congratulated on the result of the trial as far as not having been mulcted in damages is concerned; but he has unquestionably had a narrow escape, for juries in New Zealand, as elsewhere, are erratic, and more often than not their sympathies are enlisted against a medical defendant. The medical witnesses who thought that the plaintiff should have had the nature of the operation very fully explained to her were right; a prudent operating surgeon would even go a step further and obtain a written consent or a verbal one in the presence of witnesses before undertaking such an extensive proceeding.

The Annual Meeting of the New Zealand Branch of the British Medical Association.

This, the second, meeting of the above association commenced its sittings in the lecture room of the Wellington Museum on Monday, March 14th and the conference will terminate on March 19th. Considering the fact that there is a widespread epidemic of influenza prevailing all over the colony at this moment the assemblage of the profession in the "Empire City" is numerically strong. The members of the Wellington branch acting as our hosts on this occasion have taken upon their shoulders the chief task of reading the papers, thus paving the way for discussions on various topics of interest. One that is more to be fully dealt with is Dr. Cleghorn's remarks on "Private Patients in Public Hospitals." That some at least of the hospitals in New Zealand are grossly abused is an undoubted fact. Successful tradesmen and persons in sound financial positions seek and obtain admission into our hospitals for treatment as paupers when they are well able to pay for professional advice and attention outside. These persons—and they are not a few—claim as ratepayers their right to be thus treated and legally there is no redress. There is a very decided tinge of illiberality about these persons which can only be put a stop to by legislation on this important subject, for this evil is universal in this colony. Dr. Fell is the president for this year. He has been exerting himself for some considerable time past towards making this conference the success it has already attained. He has been ably backed up by other members of the Wellington branch in organising social functions of a most enjoyable character whereby the visiting medical men and their wives will be kept busy until the week is over. I hope to send you fuller particulars concerning this meeting, which is now sitting, by the next mail.

March 15th.

Obituary.

SURGEON-LIEUTENANT-COLONEL WILLIAM GEORGE SHEPHERD, M.D. ABERD., F.R.C.S. ENG.

IN Surgeon-Lieutenant-Colonel Shepherd, who died on March 30th last at the age of eighty-three years, an interesting character has passed away. Educated so long ago as when the Aldersgate-street School of Medicine flourished, where for a time he was a demonstrator of anatomy, he became a successful general practitioner in Claremont-square and afterwards in Myddelton-square, Clerkenwell, and had an aptitude for operative

surgery. Being the son of an officer in the army he had inherited a taste for military service and joined the Victoria Rifles, with which regiment he was connected for thirty-one years, first as a private and afterwards as surgeon. His genial manners and remarkable spirit of comradeship made him one of the most popular members of that ancient corps. His surgical aptitudes brought him to the front in the very beginning of the movement for improving the means of aid to the wounded. His lectures and the drill of his bearer companies were typical of a happy combination of military and surgical ability. The example which he practically set to the volunteers has been followed all over the kingdom, and the system which he was one of the first to illustrate has taken shape in the education of lay people in first aid to the wounded in multiple directions. Dr. Shepherd was a fine type of the general practitioner of the last generation—somewhat rugged but honest and thorough and a sterling friend. He kept his friends and his patients loved him.

LOUIS JOSEPH KING, M.R.C.S. ENG.

BY the death on April 15th of Mr. L. J. King, at his residence, Rivers House, Bath, the medical profession of that city has lost another prominent member. Mr. King received his medical education at the Bristol Medical School, where he gained the Suple gold medals in medicine and surgery and qualified M.R.C.S. Eng. in 1871. He was a member of a well-known Bath family and had a large and extensive practice, being consulting surgeon to the Eastern Dispensary and the Eye and Ear Infirmary. Mr. King, who was in his fiftieth year at the time of his death, had been in failing health for some months past. He was extremely popular with all who knew him and will be greatly missed in Bath. He leaves a widow and two daughters for whom much sympathy is felt. The interment took place in the Roman Catholic Cemetery at Perrymead, Bath.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Carl Nicholas, Professor of Hygiene in the University of Lausanne.—Dr. Rudolf Leuckart, Professor of Zoology and Zootomy in the University of Leipsic and well known in all civilised countries on account of his valuable researches on parasites. He was born in 1823 in Helmstedt and studied medicine at Göttingen, where he was a pupil of Rudolf Wagner in zoology. He became professor of this subject in Giessen in 1855 and migrated to the Leipsic chair in 1870.

THE NINTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.

(FROM OUR SPECIAL CORRESPONDENT.)

BACTERIOLOGY.

Pneumococci.—Intra-cerebral Inoculation.—Experiments in the Treatment of Snake bites.

WITH ten sections of hygiene and three of demography all sitting at one and the same time it is absolutely impossible to follow or to obtain anything like a consecutive idea of what has occurred in each of these thirteen different meetings; besides, such an account would fill a bulky volume, outstepping altogether the limits of a periodical publication. All I can venture to attempt is a summary of some of the more important papers and an account of some of the debates at which I was able personally to assist. As at Budapest, so also at Madrid, it is the bacteriological section which has attracted the most attention. This is not surprising, as it is in the domain of bacteriology that new discoveries were most likely to be recorded. In this respect the Congress has not been disappointed. For instance, Dr. Nocard, of the Veterinary School of Alfort (the great French centre for the production of serum) and delegate of the French Academy of Medicine, read a very important paper on the microbe of pneumonia. He had succeeded in cultivating this microbe in envelopes of collodion. These little sacks were then introduced into the peritoneum of animals, where they grew and multiplied, protected by the collodion from all surrounding hostile influences. At first limpid these sacks become opalescent when a numerous colony has grown within them and constitute a virus which will produce the malady after its tenth generation or colonisation. When examined even with the most powerful microsccpes nothing can be seen but an extremely small speck. So small is this speck that it is not possible to affirm that it is a microbe and the proof of its character is only obtained by means of inoculations. Under special conditions Dr. Nocard was able to cultivate the microbe otherwise than within the bodies of living animals and then the same opalescence appears which as yet constitutes the best practical proof we have that a colony has been developed. Having thus secured the microbe which up to now was unrecognised and invisible there is reason to hope that means will soon be found of producing a "vaccine" against this terrible cattle scourge.

Dr. Roux, of the Pasteur Institute, is unfortunately not present at this Congress and those who remember the sensation he produced at Budapest by his paper on the Anti-diphtheritic Toxin have not failed to express their regret at his absence. But he is worthily represented by his colleague, Dr. BORREL. The latter read a paper describing the experiments made by Dr. Roux and himself at the Pasteur Institute with regard to the tetanic disease obtained by the direct inoculation of tetanic toxin in the brain substance of susceptible animals. Under the name of cerebral tetanus a special malady is obtained which is clearly defined by a set of symptoms including excitement, epileptiform convulsions, strange or manifold desires, and other symptoms which vary according to the portion of the brain in which the toxin has been introduced. This tetanic malady is absolutely different to the ordinary tetanus but is none the less specific. Dr. Borrel and Dr. Roux then studied cerebral tetanus among immunised animals. They discovered that an animal rendered immune against injections under the skin was not immune against injections into the substance of the brain. From this they conclude that subcutaneous injections of antitoxin do not affect the nerve cells and do not protect them. The same occurs when for therapeutic purposes serum is injected into an animal which has commenced to manifest the symptoms of tetanus, the nerve substance being already attacked by the toxin. The serum does not reach the nerve cells and therefore the toxin can continue its deadly effects undisturbed. This explains the many failures to treat tetanus by antitoxin. Dr. Roux and Dr. Borrel then tried to treat the disease by conveying the antitoxin direct to the brain substance. They were thus able to cure rabbits, guinea-pigs, &c., even when the disease had prevailed for some hours, and this at a time when very large subcutaneous injections had proved of no use whatsoever. On the other hand, when injected into the brain matter very small quantities of serum sufficed. These researches on cerebral tetanus demonstrate that with animals immunised passively or actively the nerve cells are not immunised. An immunised animal which resists a subcutaneous inoculation of the toxin will die if the smallest quantity of this toxin is introduced into the brain matter. Immunity is not therefore due to some new property acquired by the nerve cells as they remain unaffected unless directly attacked. The same may be noticed in cases of natural immunity. Thus, for instance, Dr. Roux and Dr. Borrel have shown that the rat is naturally immune from diphtheria and that subcutaneous injections of diphtheritic poison will not produce this disease. On the other hand, if the smallest quantity of this toxin is introduced into the brain of this animal it will die from diphtheritic paralysis. All these facts open out a new field of research in respect to the question of immunity.

Dr. A. CALMETTE, who is now professor of the Pasteur Institute of Lille, but whose investigations in China and elsewhere are well known, made some interesting and conclusive experiments with regard to the venom of reptiles. He brought some rabbits in cages and the most active snake poisons known. These consisted of a mixture of the venom of the bothrops, the naja and the cobra capello. Taking one of the rabbits he injected five times the fatal dose into a vein of the ear. In twenty minutes this rabbit was dead. In the meanwhile he injected two cubic centimetres of serum into two of the other rabbits; and then after a little while injected the same dose of venom into these two rabbits which was fatal to the first rabbit. The serum, however, proved a perfect protective; the two

rabbits were not even ill. He then took two other rabbits and injected five cubic centimetres of serum into one of the rabbits. He then gave to both the rabbits ten times the fatal dose of venom. The rabbit which had not been rendered immune by the serum died in three minutes, the other rabbit, though it had received ten times the fatal dose of venom, was not affected. Professor Calmette explained that with regard to the poison of reptiles it was possible to calculate with great precision the results. According to the weight of the animal or person it could be reckoned how much poison would destroy and how much serum would save life. The production of this serum was easy and large quantities had been sent to India. It was stable in quality and could be kept any length of time. Nor did the horses employed for its production appear to be any the worse for the process, though they were bled once a fortnight—a fact which perhaps explained why our forefathers were able to withstand the frequent bleeding to which they were subjected by the medical practitioners of their day.

Mr. HERBERT E. DURHAM, of the Pathological Laboratory of the University of Cambridge, read a paper on the Micrococcus of Mediterranean Fever, in which he showed that there were special characteristics which distinguished the micrococcus Melitensis. By means of intra-cerebral inoculations the coccus becomes pathogenic for rabbits and guinea-pigs and may produce fatal results in a few days, but intra-peritoneal injections are not uniformly fatal; it often produces chronic illness. What, however, is of the greatest general and practical interest in Mr. Durham's paper is his testimony that the cocci are found in the urine of these animals a long time after the inoculation. This suggests that observations should be made on the urine of human beings who have suffered from Malta fever and similar ailments. One animal killed four months after inoculation still had the cocci in its kidney and urine, but not elsewhere. If the cocci persist in a similar manner in the urine of human beings a serious and practical question arises as to how such urine is to be disinfected, and if not disinfected what dangers may it occasion? Further, it was urged that more careful observations were needed as to the length of time the typhoid bacilli were present in the urine after convalescence and what occurs with regard to other infectious fevers. Mr. Durham also explained that the blood of rabbits and guinea-pigs which have been inoculated acquire agglutinating properties towards the pathogenic coccus. Experiments show that the presence of agglutinins is associated with a condition of the blood which is inimical to the existence of the cocci, and he described the varying agglutinating powers of the blood after the administration of different doses of the cocci.

SCHOOL HOLIDAY COLONIES.

Another section of the Congress which was very largely attended, especially by the lady members, was that dealing with the hygiene of schools. Here some very warm debates occurred; indeed, to the phlegmatic Englishman, unaccustomed to the exuberance of the South European, it seemed as if some of the Spanish delegates were violently quarrelling with each other. But the noise was only due to the enthusiasm of earnest convictions. Señor AGUSTIN SARDA, Councillor to the Public Instruction Board of Spain, caused a tremendous ferment because he pleaded that children should not have any books given them till they were eleven or twelve years old. This, he said, was necessary for sanitary reasons, as a child under that age should not work more than six hours, therefore should have no home-work. On the other hand, while the child was at school the time should be employed listening to his instructor rather than reading books. From the pædagogic point of view he urged that if young children were made to learn lessons from books they got into the habit of referring to books instead of seeking to develop their own ideas. On this comparatively inoffensive beginning the whole system of education came under criticism till at last one speaker went so far as to say that the present methods of teaching bred criminals. Of course this was violently denied and the excitement went on increasing till, from the sanitary point of view, the more appropriate subject of school colonies was introduced. On this latter subject the section voted in favour of the following resolution or "conclusions," as the declaration is called:—

Considering that holiday colonies have been established in many countries for more than twenty years by which children from the elementary schools are taken from large towns into country districts during the holidays and thus removed from the contaminating influence of the streets; that among pupils of from ten to twelve years the benefits resulting are recognised by the most eminent authorities; that these benefits comprise a greater increase in size, chest measurement, and weight gained during three weeks of country life than during six months of town life; that such a marked improvement constitutes a very valuable means of conferring vigorous health to the children; that the advantage gained from the physical and intellectual point of view continues to subsist for many months after the child has returned to town; that the habits of discipline, cleanliness, and self-control acquired in these colonies by the example given or the desire of the pupils to prove their gratitude towards those who have procured for them so agreeable a holiday are brought home by the pupils, and do not fail to influence their parents and families for good and that altogether a better tone and sentiments of fraternity are engendered; that the simple character of the life in these school colonies dispels all ideas of luxury which might corrupt the pupils; that the cost of such colonies has never exceeded 2s. 6d. per day per pupil and that for a little over £3 a pupil may be sent to a school colony for three weeks (disposable school funds could scarcely be employed more advantageously and economically);—for these and many other reasons the Sixth Section of the Congress of Hygiene expresses its desire that municipalities' school funds, cantonal delegations, &c., should take in hand the establishment of school colonies. The Sixth Section recommends this sort of institution as one of the means that is best calculated to ameliorate both the moral and physical condition of the pupils and, in some instances, of their parents.

The same section passed a resolution to the effect that children suffering from ophthalmia should not be absolutely excluded from school, but should be grouped together in a separate class-room. In hospitals, however, such cases should be relegated to a separate special wing or pavilion.

FURNISHED LODGING HOUSES.

In the tenth section, dealing with Architecture and Sanitary Engineering, M. F. Besançon, chief of a division at the Paris Prefecture of Police and member of the Council of Hygiene, read a paper on the Sanitary Condition of Furnished Lodging-houses. He expressed the hope that in all important cities special rules would be drawn up and applied to this class of dwelling. Overcrowding, a faulty disposition of the rooms, and dirt, all tended to convert such places into centres of infection. He then went on to describe the results achieved in Paris by the application of the police ordinance of Oct. 25th, 1883. This law was now all the more readily applied as the Municipal Council of Paris and the Council-General of the Department of the Seine had organised a service of medical men and of architects whose business it is to inspect and report upon the sanitary condition of furnished lodgings. The section, which was then sitting under the Presidency of the Chief Engineer of Vienna, Herr Attilia Rolla, adopted a resolution in favour of the systematic inspection of lodging-houses by a combined service of medical men and architects, considering that after the explanations given by M. Besançon the advantages of such measures could not be questioned.

WALL DISEASES TREATED BY INOCULATION.

Dr. E. VALLIN, of the French Academy of Medicine, read a very interesting and original paper on the Presence of Saltpetre in the Walls of Inhabited Houses. This he described as a disease of the walls due to the presence of micro-organisms. As the walls could not suffer without causing serious inconvenience to the persons whom they were destined to shelter it was the duty of sanitary reformers to seek to cure the walls and thus save the inhabitants of the houses. The disease was caused by the penetration into the body of the walls of the bacilli of nitrification, and consequently the houses became cold, damp, and unwholesome. This state was likely to occur in damp localities and in the presence of nitrogenous organic matter. From the sanitary point of view this disease of the walls could and should be prevented or cured as we prevent or cure virulent diseases among men and animals. Consequently, Dr. Vallin proceeded to speak of the walls of a house just as if they were human beings and went systematically through the various symptoms of their diseases. Dealing first with the prophylaxis of wall diseases he pointed out that the primary step to be taken was to thoroughly drain the ground round the walls and isolate them from the surrounding earth, if possible by a trench and by the use of cement, asphalt, or coal tar. Thus the access of water bearing nitrifying bacteria that are aerobic would be prevented. It was also very necessary to mix the mortar used with antiseptic solutions such as dissolved sulphate of copper, &c. Where these precautions had not been taken and the disease had broken out then the treatment indicated was as follows: first to scrape off and wash away all superficial traces of saltpetre, &c.; then the walls should be inoculated with active cultures of

the anti-nitrifying bacilli which impoverish farm manure by decomposing the nitrates and by throwing off in the atmosphere a great part of the nitrogen which they contain; these walls should then be covered over with impermeable paint so as to retard the process of nitrification of the aerobic germs and, on the other hand, to stimulate the growth of the anaerobic and anti-nitrifying germs which remove the oxygen from the nitrates and from ammonia when they cannot supply themselves with oxygen from the atmosphere. This ingenious theory was highly appreciated and formed the subject of many conversations among members of the Congress. The idea of applying the principles of inoculation to the preservation of material used in building opens out a vast field of possible progress in the domains of sanitary engineering and architecture.

In respect to buildings, Señor Fort, a Spanish architect, was very anxious to prevent accidents in theatres. He proposed that all the scenery should be treated with sulphate of ammonia, and that all the paint should be made with asbestos so as not to be inflammable. The structure itself should be made as much as possible of iron, and no candle or oil lamp should be allowed. The lighting, he insisted, must be carried out exclusively with electricity, and there must be two systems or separate sets of wire—one for the auditorium and the other to give light behind the curtain. Thus if an accident occurred in one part of the house it would be possible to extinguish all the lights without affecting the other part. This would be very useful in the prevention of panics.

THE RECEPTION AND ENTERTAINMENT OF THE MEMBERS.

The Congress, it will be remembered, should have been held last year, but was postponed because Spain was engaged in two colonial wars. Now these two wars are not only continuing but it is almost certain that Spain must also undertake a gigantic struggle against all the might and power of the United States of America. Under such circumstances had the Congress been postponed even at the eleventh hour no one could have complained or been surprised. The Congress, however, was not only held in spite of these terrible difficulties, but everything has been done in a most lavish manner, just as if the country was in the full enjoyment of a period of peace and prosperity. It is, indeed, true that while arming to the teeth and preparing for war not one item has been abandoned of the splendid programme prepared to honour and to celebrate the great work of peace and progress on which the Congress is engaged. To hold in so brilliant a manner such a Congress at such a moment constitutes a practical demonstration of the self-confidence and of the vitality which animates the Spanish people. Many other nations would have shrunk from such a task or would at least have cut down some portion of the programme. But even if there had been no question of war very few delegates could have expected the lavish hospitality which they have received. Spain, it is but too obvious, is a poor country and therefore the members of the Congress only anticipated, and would have been quite content with, a very modest and inexpensive reception. The study of hygiene, and not the enjoyment of banquets and receptions, is the object of the Congress. Therefore when coming to a poor country, at a moment of terrible crisis, little more was needed or expected than the possibility of meeting and of discussing. Instead of this minimum the members of the Congress have enjoyed remarkable hospitality and a princely reception. On Saturday evening, April 9th, they met in the Conservatory of Music, where a well-supplied buffet awaited them. On Sunday there was the gala performance at the Spanish theatre which I have already described. On Monday an excellent concert was given in their honour at the Athenæum Club. On Tuesday evening the Minister of the Interior gave one of the finest banquets I have ever seen in any country or at any congress. For this purpose the whole of the floor of the Grand Opera House was boarded over from the back of the stage right down to the first tier of boxes. This immense space was covered with a rich carpet. Across the back of the stage the Minister of the Interior and the official delegates of the various Governments sat facing the long rows of tables that stretched the whole length of the building. The scene on the stage was that of a banqueting hall disposed so that there were no side wings. As the floor sloped slightly it was easy to look up or down. The magnificent opera house was brilliantly illuminated throughout and, further, there were coloured limelights playing on the stage and upper table. In one of the galleries the orchestra of the opera performed various selections and, rendering the scene still more animated, a great number of ladies in evening dress and sparkling with jewellery occupied the boxes, having come to look on this wonderful scene, to hear the speeches, and to see the delegates. Of the speeches, however, nothing much can be said. It required no ordinary voice and power to be heard in such an enormous theatre and amid the inevitable noise due to such a concourse of people. Of course the Minister of the Interior spoke words of warm welcome and Dr. Brouardel, in the name of the Permanent International Committee, replied. Dr. Navarre, President of the Paris Municipal Council, responded on behalf of the French delegation, declaring that this magnificent *fête* gave the members the illusion of peace and that in any case it was a great achievement to have united at such a moment the representatives of science of all countries, for the future was with the country that knew best how to profit by the discoveries of science. The Hon. E. Lyulph Stanley, delegate of the London School Board, responded on behalf of the British delegation and was followed by Surgeon-General Macpherson of the War Office, who pointed out that a few centuries ago England sent its students to the Spanish universities and that now Englishmen had once more come, and not in vain, to seek knowledge. After speeches from the German and one or two other delegates the speech-making came to a close rather earlier than usual, as it was really impossible to command the attention of so vast an audience.

On the following day (Wednesday) all the members of the Congress were received by the King and the Queen Regent at the royal palace. When the magnificent rooms of the palace were well filled Her Majesty came out and walking through the centre of the various rooms paused to talk with various members of the Congress. Nor was Her Majesty satisfied with the mere exchange of a few complimentary words, but talked lengthily on various subjects. For instance, of Dr. MacAlister she inquired whether the gown worn by the Princess of Wales as doctor of music was like the Cambridge gown which he was wearing. Her Majesty also asked many questions as to lady medical practitioners, and then addressed Miss Beverley who is a medical student. When speaking to the Belgium delegates she was keen in her inquiries concerning the health of the Queen of the Belgians; and so on, from group to group, always finding something appropriate to say, and more often than not saying it in the language of the delegate. Quite apart from her royal attributes the Queen Regent showed herself to be a gifted with exceptional knowledge, tact and amiability. After spending more than an hour in friendly conversation with the delegates of all nationalities, the Queen Regent went to her private apartments, reappearing again shortly afterwards with the young king walking in front of her. His Majesty Alfonso XIII. bowed to the delegates on either side of him as he passed slowly through the lengthy suit of apartments. The members of the Congress were now left to refresh themselves with all manner of delicacies—ices, tea, and good wines—which were displayed on a large buffet. But what was especially appreciated was the pleasure of being able to stroll through the gorgeous suite of rooms, meeting there old friends and acquaintances. The royal reception proved to be one of the best conversaziones enjoyed during the week.

On Thursday, Friday, and Sunday nights free admittances to various Madrid theatres were distributed to the members of the Congress and on Saturday night there was the grand reception at the town hall. But apart from these official entertainments the Governor of the province, his Excellency Señor D. Aguilera y Velasco—who, by the way, was Minister of the Interior when the Congress at Budapest was invited to hold its next session at Madrid—and the Mayor of Madrid, his Excellency Señor D. Conde de Romanones, have on several occasions entertained members of the Congress, and there have been many private receptions and other marks of hospitality.

The French Ambassador gave a dinner to some of the leading French delegates and all the French delegation enjoyed a very lively evening after a dinner given to them by the French Club at Madrid. As for the British Embassy or the British residents in Madrid, if taken in their collective capacity, they have as yet made no sign of existence. Perhaps in the course of time it will dawn upon them that there has been a congress in Madrid and that they might have done something to welcome the distinguished fellow countrymen who have been in their midst.

CLOSURE OF THE CONGRESS.

The final and plenary meeting of the Congress was held in the Great Hall of the Central University. This is a magnificent oblong hall, with a lofty domed roof. The whole Congress might easily have met here and have discussed the more urgent and practical questions, instead of being split up in thirteen little sections. An expression of opinion might thus have been obtained which must have influenced considerably all concerned. Unfortunately, at Madrid the error committed in London and Budapest was repeated and there were no discussions at the two plenary meetings of the Congress. The first, held last Sunday, I have fully described and it served only for the purpose of exchanging courteous expressions and good wishes and for formally declaring that the Congress was open. The second full meeting of the Congress has again served for the purpose of exchanging compliments and to declare that the Congress was closed. What else was done can hardly be treated as serious. In the early morning the Permanent International Committee met and looked over the resolutions which had been passed in the Sections, exercising their right to expunge those resolutions which were not appropriate. As an example of such resolutions I was told that there was one condemning the boiling of milk, and it was suggested that this had been passed when the section was almost empty and the two or three persons present did not understand the subject under discussion. On Friday and on Saturday many of the members of the Congress went to the Escurial or to Toledo, so that the sections were not so well attended. Some of the sections did not meet at all, either because they had exhausted their programme or for want of a sufficient audience. Others, on the contrary, notably the section on the Hygiene of Childhood, met in the afternoon as well as in the morning, and were always well attended, in spite of the excursions and other diversions. The resolutions adopted by these different sections, after having been examined by the Permanent Committee, were read out by the general secretary to the whole Congress at the final meeting. The majority were in French, some were in Spanish. It is quite certain that the members who sat at the farther end of the hall could not hear what was said. Dr. Julian Calleja, the acting President of the Congress, was in the chair. When a resolution had been read out he inquired in Spanish whether the Congress approved and though more than a thousand persons were present barely a dozen hands were held up. This, however, was supposed to suffice, for the contrary opinion was not ever asked. The vote was therefore a mere matter of form, few persons present realising what was done. There was no discussion and no adverse vote was solicited or recorded. This is most regrettable, for a great force of scientific opinion had been gathered together and then allowed to run to waste, no emphatic expression of that opinion having been obtained.

The resolutions having been thus hastily disposed of, Dr. KÖHLER, as one of the official representatives of Germany, rose to express the satisfaction which his fellow countrymen had experienced during their visit to Spain. The speech, delivered in German, was, however, concluded by a few appropriate and complimentary sentences in Spanish, which were much appreciated.

Professor BROUARDEL followed. He said that the hopes they had entertained that the Congress would bear good fruit had been more than realised. The King, the Queen-Regent, all the authorities had helped to give the delegates a reception which had not been surpassed in any country. They had come to work for the happiness of mankind and for peace. Those who sought to improve the health of the populations could not but view with horror the preparations for war. He hoped that peace would be maintained, as nothing could be more distressing than to see those eminent medical men with whom they had worked harmoniously at many Congresses at war with each other. The results of the Congress would be all the more beneficial as the sense of continuity which at first did not exist had now been strongly emphasised. The Permanent Committee had voted that the next Congress should be held in Paris in the year 1900. In the name and with the authority of the French Government he assured all present that every effort would be made to render the Paris Congress worthy of the Congress of Madrid.

Dr. DONALD MACALISTER of Cambridge spoke on behalf of the British members. It was sometimes said, he remarked, that people from the north were cold, close, and unexpansive, but their visit to Madrid must have opened the closest heart and made warm the coldest blood. They could never forget how they had been received, especially by the Queen Regent, who had shown herself to be a noble, able, queenly woman. The reception given by others, though not so striking, was yet a cause of surprise and admiration. The strain put on the general secretary, Dr. Amalio Gimeno, was immense and yet throughout he preserved his kindly and courteous disposition. His example must never be forgotten in the organisation of future congresses. To all who with the general secretary had by their work contributed to the success of the Congress he tendered the thanks of the British members. The British members had done good scientific work but, better still, they had made valuable friends. They would leave Spain with a keen appreciation of its heart, its love of science, and its dignity as a nation.

Professor PAGLIANI, speaking eloquently on behalf of the Italians, alluded to the soft and amiable voice of the Queen Regent, and to the friendships formed. The Spanish types painted by Murillo, Velasquez, or Goyas had now been seen in life as well as on canvas, and he united with his colleagues in thanking the nation which had produced such great artists and had rendered so many services. As for war, Spain had waged its war of independence, boasted of its Maid of Saragossa, and was in no need of further military glory. But the death-rate of the country was still high and what was needed was further progress in practical hygiene; they must march, march forward.

Dr. VON JURASCHEK expressed thanks in the name of Austria, and Dr. CORNÉL CHYSER on behalf of Hungary.

Dr. ATTAMINANO, a Mexican delegate, elicited loud applause by calling Spain his mother country, and the Portuguese delegate, Dr. Amado Silva, was equally appreciated when he concluded his speech, delivered in French, with the cry of *Vive la paix honourable*.

After a few words from a Dutch delegate another ovation greeted Dr. HÉGUY, delegate of Uruguay, South America, for he also expressed the warmest sympathy with the Spanish people in their present difficulties, concluding by wishing "prosperity to the mother country and the Spanish people."

The Governor of the province of Madrid, his Excellency Señor D. AGUILERA Y VELASCO, now came forward to express his gratitude to the distinguished men of science who had come from all parts of the world to constitute in Madrid the grand assembly which had honoured the capital by its presence.

The Secretary-General, Dr. AMALIO GIMENO, followed by saying a few words in acknowledgment of the thanks he had received. There were some 2000 members of the Congress, so that it was not inferior to that held at Budapest. As for the work he had done, he was only the figurehead. Others less in evidence had worked as hard.

These modest remarks were much applauded, for everyone knows how greatly the Congress is indebted to the organising capacity and the active leadership of the Secretary-General.

The Acting President, Dr. JULIAN CALLEJA, was the last speaker. He apologised for the absence of the Minister of the Interior, detained by urgent affairs of State. This, in the present crisis, would be easily understood and forgiven. The Minister had, however, sent his profound thanks to the distinguished foreign visitors who had helped to constitute this magnificent Congress. He hoped that they would recognise that Spain was devoted to the cause of science and progress—that Spain listened to all that is said on behalf of suffering humanity. Science, progress, peace, friendship, such, said Dr. Calleja, were, in a few words, their programme. Finally, he declared that the next Congress would meet in Paris in 1900 and that the present Congress had terminated its labours and was now closed.

THE PRESS BAZAAR IN AID OF THE LONDON HOSPITAL.—A committee meeting was held in the Oak Room of the Hotel Cecil on Wednesday afternoon, at which Mrs. Spender presided, to consider the organisation of a Press Bazaar in Aid of the London Hospital. It was suggested that June 28th or 29th should be fixed as the date for holding the bazaar. Some sixteen or eighteen newspapers have already signified their willingness to hold stalls and to help in making the exhibition of objects connected with the press an attractive one.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having previously passed the necessary examinations and having now attained the legal age of twenty-five years have been admitted Fellows of the College, viz.:

Edward Owen Thurston, M.B., B.S. Lond., L.R.C.P. Lond., St. Thomas's Hospital; diploma of Member dated Nov. 8th, 1894; Charles Herbert Fagge, L.R.C.P. Lond., Guy's Hospital; diploma of Member dated Aug. 4th, 1886.

UNIVERSITY OF DURHAM.—At the second examination for the degree of Bachelor in Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in April, the following candidates satisfied the examiners:—

Anatomy, Physiology, and Materia Medica.—Second-class Honours: Leslie Herbert Walsh, M.R.C.S., L.R.C.P., King's College Hospital; and Edward Turner Born, College of Medicine, Newcastle-upon Tyne. *Pass-list:* Robert Story Brown, George Burrows Brown, and Joseph James French, College of Medicine, Newcastle-upon-Tyne; Richard Denington Fisher, M.R.C.S., L.R.C.P., London Hospital; Howard Payne Fox, Cooke's School of Anatomy; Charles Henry Gibson, Hubert Wolstenholme Horan, and James Willie Heslop, College of Medicine, Newcastle-upon-Tyne; David Henry Jeavons Kirton, Mason College, Birmingham; and John Robert Mitchell, Ralph Thomas Vaux, and Frederick Percy Wigfield, College of Medicine, Newcastle-upon-Tyne.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. E. Lexer, Dr. G. Joachimsthal, and Dr. Wolpert have been recognised as *privat-docenten* of Surgery, Orthopædic Surgery, and Hygiene respectively.—*Catania:* Dr. Giuseppe D'Abundo, Extraordinary Professor of Psychiatry, has been promoted to be Ordinary Professor.—*Göttingen:* Dr. Karl Jacobj has been appointed to the chair of Pharmacology in place of the late Dr. Marmé.—*Heidelberg:* Dr. E. von Hippel, *privat-docent* of Ophthalmology, has been promoted to be Extraordinary Professor.—*Lemberg:* Dr. W. von Lukasiewicz, Extraordinary Professor in Innsbrück, has been appointed to the chair of Dermatology and Syphilis.—*Leipsic:* Dr. Perthes, Assistant in the Surgical Clinic, has been recognised as *privat-docent*.—*Munich:* Dr. Wilhelm Herzog, *privat-docent* of Surgery, has been promoted to be Extraordinary Professor.—*Padua:* Dr. Angelo Ceconi has been recognised as *privat-docent* of Medical Pathology.—*Pisa:* Dr Alberto Cavazzini has been recognised as *privat-docent* of Medical Pathology.—*St. Petersburg (Military Medical Academy):* Dr. Gundobin, *privat-docent* of Children's Diseases, has been promoted to be Extraordinary Professor. Dr. Bellarminoff, Extraordinary Professor of Ophthalmology, has been promoted to be Ordinary Professor.—*Zürich:* Dr. Eugen Bleuler has been appointed Professor of Clinical Psychiatry in place of Dr. Forel, who has resigned. Dr. Cloetta has been recognised as *privat-docent* of Pharmacology.

AT the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, held on the 12th inst., Mr. W. H. Lloyd, M.D. St. And., Inspector-General, in the chair, the sum of £61 was distributed among the several applicants.

LITERARY INTELLIGENCE.—Mr. H. Wippell Gadd, of Messrs. Evans, Gadd and Co. of Bristol, is preparing for the press a small book entitled, "A Pocket Synopsis of the British Pharmacopœia, 1898," containing concise notes on the changes that have been introduced in the new issue, with particulars of the added preparations and tables of doses and strengths.—Sajous' "Annual of the Universal Medical Sciences" will be published within a few days by Mr. F. J. Rebman, 11, Adam-street, Strand, W.C.—Messrs. Charles Griffin and Company, Limited, will issue immediately a new edition, revised and enlarged, of Professor Dixon Mann's "Forensic Medicine and Toxicology" and a translation of "Technical Mycology for Bacteriologists and Analysts," by Professor Franz Lafar of Vienna, from the pen of Mr. Charles T. C. Salter. They have in the press a new edition, revised and enlarged, of Mr. Bevan Lewis's "Mental Diseases, with Special Reference to the Pathological Aspects of Insanity," and an English edition of the new "Atlas of Urinary Sediments," by Dr. Hermann Rieder of Munich, with a translation of the accompanying letterpress by Dr. Craven Moore, edited and annotated by Professor Sheridan Delépine.

THE London Hospital has received in response to the special appeal now being made in aid of the Maintenance Fund donations of £500 from "Anonymous," £500 from "J. A. F.," £100 from Mr. C. E. N. Charrington, £100 from Lord Grimthorpe, £105 from Mrs. Graham Robertson, £200 from "E. M. G.," Brighton, and several others of £100 and £50.

A COMPLIMENTARY DINNER.—At the Inns of Court Hotel, Lincoln's Inn-fields, on April 18th, there was given by the Infirmary Medical Superintendents' Society a dinner in honour of Mr. D. M. Forbes, who has retired from the service and is leaving Shoreditch Infirmary after more than thirty years' tenure of office. Mr. Burney, the chairman, proposed the health of the guest in suitable terms, and he and Mr. Hopkins, Mr. Lunn, Mr. Gordon and Dr. Toogood paid a high tribute to the good work achieved by Mr. Forbes in the interests of the sick poor, and pointed out that not only was he the pioneer in the establishment of the separated infirmaries under medical control, but also, as Mr. Hopkins explained, one of the first to draw attention to the fearful mortality amongst London lead-workers and to recommend preventive measures, the advocacy of which very materially led to the passing of the Lead Workers Acts which have been the means of saving many hundreds of lives. Mr. Forbes returned thanks in an appropriate speech.

NORTHUMBERLAND COUNTY NURSING ASSOCIATION.—This useful association has recently issued its first annual report. Its most important item is the announcement that affiliation to the Queen Victoria Jubilee Institute for nurses has been made. There are two classes of nurses, first-class or Queen's nurses, of whom four are at present employed, and second-class or village nurses, of whom eight are employed. The donations and subscriptions do not as yet amount to a very large sum, but there can be no doubt that as the association becomes better known and the services of the nurses thoroughly appreciated money will be forthcoming. The County Council contributes to the funds of the association and gives scholarships to certain nurses between twenty-five and forty years of age having satisfactory medical and other references and being resident in the county of Northumberland. The Countess Percy is president and on the General Committee are the names of many well-known medical men practising in the county.

THE NEWCASTLE DISPENSARY.—At the annual meeting of governors held on March 17th the 120th report was read and it showed that 27,916 cases had been treated during the year, being an increase of 2955. The financial statement showed a balance of £47 in hand. A special vote of thanks was returned in the report made by the resident medical officer, Dr. W. Hardcastle, to the Cathedral Nurse and Loan Society, to the Brunswick and to St. James's Congregational Nurse Deaconess Societies. The amount of gratuitous medical aid given in Newcastle during 1897 was very large. 27,916 cases were attended to by the Dispensary and 40,558 by the Royal Infirmary, being an increase over the previous year of 6134—that is to say, 68 474 cases were dealt with by these two charities—and there are several others, the Children's, the Skin, the Eye, the Chest, the Woman's, the Lying-in, the Throat and Ear, and the Dental Hospitals in the city. The medical may well be a poor profession.

THE HOSPITAL SATURDAY FUND.—The twenty-fourth annual report of this fund, which has just been issued, shows the receipts for the year to be as follows: Workshop and business house collection, £16,615 5*s.* 8*d.*; street collection. £3330 11*s.* 10*d.*; donations, £65 16*s.*; interest, £33 9*s.* 3*d.*; ambulance (donations, sales, and fees), £86 12*s.* 9*d.*; miscellaneous, £6 19*s.* 4*d.* The workshop and business house collection shows an increase of £278 and the street collection a decrease of £1554. As we have previously announced, the Council of the Fund have very wisely decided to do away with the annual street collection and in lieu thereof a private collection will be made extending over some weeks. The results of this collection will be gathered up on one particular day (this year Sept. 3rd), to be called Hospital Saturday as heretofore. The total income for the year 1897 was £20 138. as against £21,614 in 1896. The total sum awarded was £17,627 2*s.* 1*d*, as compared with £18,109 18*s.* 8*d.* last year. The number of participating institutions was 169, being a decrease of 9 compared with the numbers of the year 1896.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At a meeting of the College held on Friday, April 15th, the following gentlemen were admitted:—As Fellows: John Campbell, J. H. R. Glenn, W. L. Symes, and T. H. Wilson. As Member: W. R. Dawson.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The last monthly meeting of this society was held at 235, Lavender-hill on April 13th, under the presidency of Mr. T. A. I. Howell. The President read notes of cases of Pneumonia, Pleurisy, and Rheumatic Fever. There were shown for Mr. Charles Ryall specimens of Uteri removed for fibro-myoma, carcinoma, and epithelioma; Dr. Barkwell showed a Penis removed for malignant disease; Mr. T. J. Bokenham gave an interesting demonstration of Widal's Test for Enteric Fever which was followed by a discussion, in which Dr. B. L. Abrahams, Mr. Gay, and others took part; and Dr. Mackintosh showed a series of lantern slides of the Commoner Micro-organisms. The usual votes of thanks brought the meeting to a close.

A LINK WITH THE PAST.—Dr. James Paul, who died not long ago at his residence, Lonsdale-villas, Barnes, had in the course of his long life witnessed many surprising innovations and advances in medicine and surgery. He took the diplomas of M.R.C.S. Eng. and L.S.A. in 1824 and almost immediately entered the naval service of the East India Company. In 1830 he settled in practice in London, where he acquired considerable reputation in connexion with the diagnosis and treatment of cholera, having been among the first to identify the disease on its appearance in 1832, and his services were consequently in request during the successive epidemics of cholera up to the memorable one of 1854. In 1833 Dr. Paul graduated as M.D. at Glasgow University. He retired from practice in 1856 and had the misfortune to lose his sight in 1881.

PRESENTATIONS TO MEDICAL MEN.—Mr. James Broomhead, M.B. Aberd., of Haslingden, the lecturer to the local ambulance classes, has been presented with thirteen volumes of the Waverley Novels in the Centenary Edition, and, having recently received twelve volumes from a ladies' ambulance class, this gift completes the set.—Mr. J. O'Neill, L.R.C.P., L.R.C.S. Edin., of Leeds, has been the recipient from the St. John Ambulance class in connexion with the North-Eastern Railway Goods' Department, Marsh-lane, of a gold-mounted umbrella as an acknowledgment of his services as instructor.—On Monday, April 4th, the members of the St. John Ambulance classes at Newtown, N. Wales, presented Mr. Anthony Lavery, L.R.C.S., L.R.C.P. Edin., with a timepiece and pair of vases in recognition of his gratuitous services to them as lecturer. On the following day a deputation waited upon Mr. Lavery to present him, on behalf of some of his patients and friends, with a consulting desk and chair on the occasion of his leaving Newtown.

DIPHTHERIA IN LONDON.—The deaths from diphtheria in London during the three weeks ended on March 26th were 33, 36, and 53 respectively. In the next succeeding week, ended on April 2nd, the total was 45, a figure nevertheless in excess by 11 of the corrected decennial average for the particular week. All 45 deaths were of young persons aged under twenty years, and 32 were of children aged from one to five years, only 3 being of infants. Both St. Pancras and Wandsworth sanitary areas had 5 deaths; Lambeth and Plumstead each had 4; and Hackney had 3 deaths. In the Outer Ring the registered deaths numbered 15, as many as 8 belonging to West Ham district. There were in London hospitals at the close of the week 1009 patients ill of diphtheria. In the week ended April 9th the deaths from the disease in London fell to 29, and were 4 below the corrected decennial average for the week. All were of young persons aged under twenty years, 3 being of infants and 15 of those in the first quinquenniad of life. There occurred 5 deaths in Hackney and 4 in Camberwell sanitary areas. In the Outer Ring 13 deaths were registered, West Ham district being credited with 5 of them. Last week there was a slight rise in the number of registered deaths from diphtheria in London, 34 being the total, as compared with 35 as the corrected decennial average for the corresponding week of the period 1888-97. Hackney again had 5 deaths placed against it and Islington was credited with 4 deaths. Only one of the 34 deaths was of a person aged over twenty years, 2 were of infants, and other 21 were of children under five years of age. In the Outer Ring the total rose to 21 deaths, of which 9 belonged to West Ham district, and 3 each to Croydon, Dartford, Hendon, and Edmonton registration areas.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the society was held on April 13th, at 11, Chandos-street, Dr. Pollock being in the chair. Four new members were elected and the deaths of two were reported. Applications for grants were received from 50 widows, 12 orphans, and 6 recipients from the Copeland Fund, and it was resolved that £1241 should be distributed among them at the next court. The expenses of the quarter were £50 15*s.* 6*d.* The treasurer was empowered to purchase stock to the amount of £500. The secretary was instructed to forward to Miss Quain a letter of sympathy and condolence on the great loss she had sustained through the death of Sir Richard Quain. The following gentlemen were nominated for election at the annual general meeting to fill the vacancies in the list of officers: Mr. Warrington Haward as treasurer in the place of the late Sir R. Quain; and Mr. C. F. Keele, Dr. Bate, Sir A. Garrod, Mr. Hazel, Mr. Lynch, and Dr. Cullingworth as directors in the place of the six seniors who retire. The annual general meeting of the society will be held on May 20th, at 5 P.M., at 11, Chandos-street, W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Lead Poisoning in the Potteries.

THE Home Secretary has determined to appoint an inspector for the district in the potteries where lead poisoning is rife and representations are being made to him in favour of a female inspector being appointed on the ground that the people who suffer most are women and girls.

Pharmacy Acts Amendment Bill.

In connexion with the Committee Stage of the Pharmacy Acts Amendment Bill, Mr. Cross, one of the Members for Glasgow, has given notice that he will move to insert the following clause, viz.: "That nothing in this Act nor in the Act to regulate the sale of poisons, 31 and 32 Vict. c. 21, entitled The Pharmacy Act, 1868, shall apply to or interfere with the business of persons who are engaged in the sale, distribution, or manufacture of insecticides, destroyers of vermin, or disease germs in plants, of ant destroyers, of preparations for prevention of disease in potatoes, grain, or other field or garden crops, or for the preservation and protection of plants from disease in greenhouses or in the open air, or for other such or similar purposes, or of sheep dips or wool dressings or other articles used for such purposes."

Vaccination Bill Debate.

The debate on the second reading of the Vaccination Bill was carried on at some disadvantage in the matter of time. The House usually meets at 3 o'clock and on Government days the whole time from then until midnight is available for Government business, but on this particular occasion there was what is called at Westminster a morning sitting, which begins at 2 o'clock and ends at 7 or a few minutes before that hour. It was thought that such a sitting would suffice for the second reading of the Vaccination Bill, but as a matter of fact, owing to private bill business and questions to Ministers, the measure was not reached until shortly before 4 o'clock, and when it was reached so many Members gave evidence of their desire to speak, and those who caught the Speaker's eye occupied so much time, that it soon became apparent the stage could not be completed at that sitting. In the three hours available seven speeches were delivered, four for and three against the Bill, the longest speech being that of Sir William Priestley, which occupied considerably over an hour. When the debate will be resumed is difficult to say, for when a start is made with the committee stage of the Irish Local Government Bill next week it will be taken *de die in diem* until finished.

HOUSE OF COMMONS.

TUESDAY, APRIL 19TH.

The Report of the Tuberculosis Commission.

Mr. Chaplin, answering a question on this subject addressed to him by Mr. Field, said he had made inquiries of the Home Office and he was informed that the report would probably be presented that day.

The Vaccination Bill: Second Reading Debate.

The first order at this sitting of the House was the Vaccination Bill of the Government.

Mr. Chaplin, as the Minister in charge of the measure, formally moved its second reading.

Sir Walter Foster said that the Bill was an exceedingly small product

of the long and laborious inquiry of the Royal Commission on Vaccination. He did not, however, complain of the smallness of the Bill. On the contrary, he thought that probably the President of the Local Government Board had exercised a wise prudence in making the measure so small as it was, for in that way he had avoided possibly some difficulties and criticisms which might interfere with the easy passage of the Bill. He would deal first with the main provisions of the Bill and afterwards with certain serious omissions to which he wished to call attention. The Bill was really an attempt to introduce a new means of applying vaccine matter to children for their protection against a serious disease. It was a State experiment upon a large scale with a new form of lymph, which was known under the name of calf lymph, but which by the scientific investigations of a distinguished medical man had been altered to such a form that while it not only attained greater efficiency than the old form, it also was not likely to convey such foul disease, as had been so often described in this House, or erysipelas or tubercle. The discovery which had been made by Dr. Sydney Monckton Copeman was that by mixing the lymph taken from the calf with glycerine they were able to obtain from a single calf vaccine sufficient to vaccinate from 4000 to 6000 children. Abroad it had been found possible to obtain sufficient to vaccinate as many as 15,000 children. And this vaccine matter mixed with glycerine was not only efficacious for the purpose of vaccination, but it contained no possibility of contamination by syphilis. One advantage it had in addition to those he had described was that it could be preserved for a considerable time without losing any of its efficacy. The new lymph was to be used under different conditions from those under which vaccination had hitherto been performed. The Royal Commission recommended that the age up to which children should be vaccinated should be extended; their recommendation mainly was that the age should be extended to six months. The Commission found that in Scotland deaths from vaccination were much more rare than in England. Deaths from vaccination were very uncommon in England, but the figures showed that while in England and Wales one death occurred in 14,159 vaccinations, in Scotland there was only one death in 38,872 vaccinations. The probable cause, or at all events one of the causes, of that was that the age in Scotland was six months, whereas in England it was three months. The Commissioners thought that an extension of age to six months would be advisable in the interest of vaccination and of the children. They also found that the extension of age was no serious deterrent as regarded the number of children vaccinated. The general feeling in this country was that early vaccination was useful because so many children did not escape vaccination as would if a longer time were allowed. In Birmingham, where vaccination was very well attended to, it was found that about 10 per cent. of the children were lost by removals during the first three months and the opinion of some people was that if the age were extended, as proposed in the Bill, to twelve months they would probably lose nearly 50 per cent. by removals. From the point of view of the efficiency and universality of vaccination that was a strong objection to the extension of the age, but at the same time he thought the advantages of vaccinating children at a later age were so great that they ought not to be deterred from extending the age to six if not to twelve months. There was no doubt that if they could make vaccination less perilous to the children they would find less objection to the operation on the part of the parents. The institution of domiciliary vaccination by the Bill had also attracted a great deal of public attention. The present system of requiring children to attend at vaccination stations for vaccination by public vaccinaters was in many ways objectionable. It brought a crowd of children into one locality which often occasioned the spread of contagious diseases and kept the mothers waiting for a long time under unfavourable conditions. But, on the other hand, he did not think that the vaccinators would be quite pleased in having to visit the children at their homes. In some towns, like Leicester and Birmingham where a strong feeling against vaccination existed, the domiciliary visits of the vaccinators would not be altogether free from difficulty and discomfort. He therefore hoped that the vaccination stations would not be entirely dispensed with. Dealing next with the provision as to penalties, Sir Walter Foster said that anyone who studied carefully the report of the Royal Commission would come to the conclusion that it practically killed compulsion. The Commissioners were of opinion—and, he thought, rightly of opinion—that the repetition of penalties for non-compliance with the law was irritating, and was probably the cause of much of the agitation against vaccination. The administration of the law was in the hands of the boards of guardians—popularly elected authorities—and as one-fifth of the boards were opposed to the compulsory clause of the present Act and refused to carry it out the law probably did more harm than good. The sincere and honest objector was not likely to be compelled by fines and imprisonments to accede to the vaccination of his children; and the report of the Royal Commission suggested as an alternative to the system of repeated fines that a person who refused to comply with the law might make before a magistrate a declaration that he had a conscientious objection to vaccination. He was sorry the right hon. gentleman had not accepted that alternative. The agitation against vaccination had undoubtedly been fostered by injudicious compulsion. Twenty per cent. of the children in England and Wales were not vaccinated, and in a large proportion of the 80 per cent. of vaccination cases recorded the vaccination was inefficient and practically useless for the protection of the children, for there was a certain class of medical practitioners, he was ashamed to say, who were willing to carry out a sham and ineffective vaccination at the request of parents and to give a certificate. That was the reason why a large number of people who had been inefficiently vaccinated got small-pox and thereby brought the whole system of vaccination into discredit and disrepute. He therefore hoped that the Local Government Board would take powers under the Bill to secure that vaccination, whether carried out by public vaccinators or by private practitioners, should be done in such a way as to be an effective protection against the disease it was intended to prevent. He considered that the position of the Government in this matter of penalties was extremely illogical and absurd. It enabled a man who paid two penalties to escape the duty he owed to the law. He considered that if a man conscientiously objected he ought to be allowed to go to a court and before a magistrate make a declaration. He thought if this were done and compulsion abandoned the law would be much more effectively administered and there would be much less dissatisfaction throughout the country. He did not propose to vote against the second reading of the Bill, because he thought that even as it stood it was an improvement on the existing law, but he hoped that in Committee they would have an opportunity of moving the omission of the section, or a portion of it, which dealt with the penalties so as to bring about the alternative he had suggested. If they could repeal the penalties altogether he should be glad, because he believed that that would make vaccination more popular. He thought that those sections which enforced penalties, and went on to imprisonment, had done a great deal of harm to the cause of vaccination. He would now refer to the omissions in the Bill. He regretted in the first place that there was nothing said about revaccination. He did not want to make revaccination compulsory but he wanted to see some system under which revaccination would be offered to the whole community at suitable times. Sir Walter Foster referred to what has been done in Germany and Italy in this connexion and to its effect on the small-pox mortality and expressed the hope that the President of the Local Government Board would turn his attention to the point and allow some clauses to be introduced into the Bill by means of which revaccination might not be forced but might be offered in the case of children leaving or entering school at twelve or fourteen years so that we might have this great protective influence in this country. The Bill gave large powers to the Local Government Board of modifying the regulations of vaccination officers; he should like that power extended in respect to all persons who vaccinated, so that they might bring under the same rules all private practitioners, and he hoped that in committee the right hon. gentleman would be willing to give even larger powers to the Board than were proposed. In conclusion Sir Walter Foster said he hoped that the President of the Local Government Board would have the credit before the Bill was passed not only of having done something to improve vaccination by the introduction of this new glycerinated lymph but of having done something to make the law more popular and efficient and so contributed to the general well-being and health of the community.

Sir William Priestley said he had listened with great pleasure to the admirable speech of his friend, and he agreed with almost all that he had said. He wished to congratulate the President of the Local Government Board on having had the courage to grasp so thorny a subject as vaccination, and though this Bill only dealt with the fringe of the subject, he regarded it as a genuine attempt to do something by way of improving the system of vaccination. He would criticise the Bill not in a hostile spirit, but rather in the hope of being able to strengthen the hands of the Government and of the President of the Local Government Board. It was computed that at present about a third of all the children born in England and Wales were escaping vaccination—i.e., about 300,000 children—and in this connexion they could not but recollect the serious object-lesson recently presented by Gloucester. The discovery of glycerinated lymph was made in 1891, and yet it had never been adopted systematically in this country. It was most likely, if once adopted, to remove many of the objections and apprehensions of parents, which he had no doubt were very conscientious. It had been adopted in other countries, where they had Ministers of public health and where a great deal more attention was paid to the question of public health than was the case in this country. The system had been carried out at Berlin, Paris, Geneva, and other centres, and as yet there had been no misadventures. The diseases most feared by parents in the matter of vaccination were syphilis, erysipelas, and tubercle. He believed the fears as to diseases being communicated by vaccination had been greatly exaggerated. The Royal Commission in their report stated that in some instances syphilis had been communicated by vaccination, but it could not have been so communicated to any substantial extent, whilst it was extremely rare for erysipelas to be conveyed at the time of vaccination. The Commission also found that there were no facts to warrant the assertion that increase of tubercle was due to vaccination. Admitting that harm was done by the practice of vaccination it was not easy at any time to do a vast amount of good without some modicum of harm. All medical efforts were relative; if they were absolute no one would die. If they were to look into the history of many remedies they would find that misadventures came by their use. It was well known, for instance, that no one could avail himself of the administration of chloroform to relieve pain without fear of misadventure. In regard to those domestic remedies Epsom salts and castor oil the effects had gone in some cases much further than had been intended or expected. The great thing in the use of all remedies was to do the greatest amount of good with the last possible harm. It was entirely a question of proportion. Unfortunately there were always people possessed of what he might be permitted to call the "anti" mind, who, with a perverse ingenuity, fastened on the harm and refused to look on the other side of the question. A distinguished scientific friend of his once said he always tried to teach his pupils to think to scale as well as work to scale; but these people who were always dwelling on th harm did not think to scale. They concentrated all their attention upon the mischief and they came signally to grief in their reasoning. Sir William Priestley then went on to express approval of the proposed domiciliary vaccination, although at the same time he hoped that stations would not be abolished altogether. Medical officers under the proposed system would have better means of persuading parents to submit their children to vaccination and of showing that objections were really not valid. It had been said that vaccinators might be very unfavourably received, and in some instances be in danger of violence from anti-vaccinationists; but in Chicago, among a population made up of all sorts and conditions of men, a system of domiciliary visits had the best possible effect, few children remaining unvaccinated. Some years ago, he had been informed, it was the custom in France to pay a small sum to parents who brought their children for vaccination, and it was surprising to find how parental scruples about danger to children were removed by the few sous paid. It was desirable that some arrangement should be made whereby medical men who vaccinated their own poor patients should receive the fee otherwise paid to the public vaccinator. To the extension of the limit of age he saw no objection so far as danger to children was concerned, for experience had shown that infants under twelve months were unlikely to take small-pox. There were some objections, but they might be overcome. True there was more risk that the vesicles might be rubbed and contaminated when the child crawled about and in twelve months removals made the following-up of the cases difficult. On the whole, he was disposed to adopt the suggestion of six instead of twelve months and the prac-

tice in Scotland and England would then be uniform. We might also imitate the practice in Germany, which obtained also in Chicago, and impose some check on the admission of unvaccinated children to school. With regard to revaccination, for which there was no provision in the Bill, Sir William Priestley said that Dr. Jenner fell into the mistake of supposing that he had found a remedy for the whole life of the patient; but observation had abundantly proved that when ten or twelve years elapsed after vaccination, though the operation might modify the effect of the disease, it was not a preservative against small-pox. Anti-vaccinationists made capital out of the fact that in outbreaks of small-pox many victims had been vaccinated, but they omitted to say how large a proportion had never been revaccinated. It might seem hard to impose an obligation on parents to which they objected and of which they did not see the value. But the object of the State should be the welfare and happiness of the greatest number and the good of the children, above all things, should be the regard of the State as well as of the parents. The danger of allowing a large number of children to remain unvaccinated had been very clearly seen at Gloucester and he would venture to point out that in proportion to the stringency with which vaccination was carried out so was protection furnished to the community. Medical men thought that vaccination was just as essential to the welfare of the child as the provision of food and raiment. If it kept the child from disease—and they believed it would—there ought to be no remission of penalties. At any rate if there were remission of penalties there ought to be something which was almost equally efficacious. He should be disposed not to remit penalties, but if the parent had conscientious objections to vaccination he would not give it up altogether, but suspend it for a time—say until the school days. This would be a great deal more logical than remitting the penalties. He would make one other suggestion. All parents who insisted that their children should not be vaccinated and who persisted in this course even after being fined once or twice should be compelled to subscribe to isolation hospitals. Isolation hospitals had been again and again proposed as an alternative to vaccination and no doubt they were the next best things, though they would not take the place of vaccination. The administration of the law, he thought, should be entrusted to the sanitary authorities and not to the boards of guardians, who had constantly shirked their duty in this connexion.

Mr. Thomas Bayley, member for the Chesterfield division of Derbyshire, moved the rejection of the Bill. He said that the House was entitled to know what it was going to cost the local authorities to carry out this Bill and upon whom the burden of payment was to fall. They might be pretty certain that if people had a choice between taking their children to a public institution for vaccination and having them vaccinated in their dwelling houses they would choose the latter course, and he would like to know what was to be the cost of this domiciliary vaccination. He submitted that the recommendations of the Royal Commission were not carried out by this Bill. The Commision reported that there were other things besides vaccination to be depended on for extinguishing small-pox. They recommended a complete system of compulsory notification, immediate hospital isolation, and improved sanitation. Not a word about those things was to be found in the Bill. A year ago he was as strongly in favour of vaccination as any one, but the reading of the official reports had now made him very doubtful on the subject. He believed that we were beginning at the wrong end, and that sanitation, isolation, and cleanly habits among the people would do more to destroy small-pox than any amount of vaccination. As to Gloucester, which he had himself visited at the time of the epidemic, the drainage of the city discharged into the Severn and was carried up by the tide beyond the pumping station where the water was pumped into the main. The people of Gloucester had thus been using contaminated water for washing and drinking.

Mr. Monk, the representative of Gloucester, interrupting the hon. Member, said it was not the case that water was taken from the Severn for drinking purposes.

Mr. Bayley said he was told that the water pumped from the Severn was the ordinary drinking-water, and he would point out that when the new waterworks were opened the epidemic disappeared. Then there was the case of Middlesbrough, which had a larger percentage of vaccinated persons in its population than any other town in the kingdom. Nevertheless, Middlesbrough had suffered a very serious outbreak of small-pox. The Bill was one which would please nobody. The Commission wished to see a less severe law put into force uncompromisingly; but this Bill would not be put in force in Leicester, for example, at all. The penalties of fine and imprisonment still remained, though they could only be inflicted once; but it was still possible to punish a man indefinitely by the constant adjournments which would be possible in the hearing of the case. The poor man who had an honest objection to vaccination would thus be liable to the loss of many days' employment. The number of those who were honestly opposed to vaccination was already large, and would certainly grow unless the decision of the individual were left perfectly free. The real question of interest to the House and the country was whether they were to continue almost the last of the old worn-out systems of imprisonment and fine for conscientious opinion rightly or wrongly held and held firmly by many people.

Mr. Steadman, Member for the Tower Hamlets Division of Stepney, seconded the motion for the rejection of the Bill. He said he was a member of one of those boards of guardians in the East-end of London which absolutely refused to carry out the present Acts of Parliament dealing with vaccination. He denied that the decrease in small-pox was due to vaccination, whatever medical men might say. Taking the last five years during which the Mile End board of guardians had refused to carry out the Vaccination Acts he found that in 1893 there occurred in that district 116 cases of small-pox and 8 deaths; in 1894 42 cases and 4 deaths; in 1895 49 cases 1 death; in 1896 1 case and no death; and in 1897 no cases at all. In Mile End no candidate for the position of guardian, whether Conservative or Liberal, stood any earthly chance of being elected unless he was opposed to compulsory vaccination. Not only so, but the attitude of the Mile End guardians had converted their brethren in the adjoining districts of Bethnal Green, St. George's-in-the-East, Poplar, and Whitechapel. All those boards to-day were absolutely refusing to carry out the Acts. There were in Mile End 16,000 children unvaccinated, and out of the 13 deaths which had occurred in the last five years 4 were through children being vaccinated. If that statement were disputed he held in his hand the certificate of the death of one of those children in which the death was laid at the door of vaccination. Through the whole of the East-end of London there were 25,131 children who were born during 1896 in ten Parliamentary divisions and out of that number only 7980 were vaccinated. He claimed that the decrease in small-pox was due more to the Public Health Act which passed this House in 1891 than to compulsory vaccination. Previous to that time the vestries were largely monopolised by the housemongers whose sole object was to evade the sanitary laws, and the sanitary inspectors were practically under their thumb, and it was not till the Public Health Act came into operation that they were able to compel the local authorities to do their duty as regards sanitation. Isolation in conjunction with better sanitary arrangements had been the means of preventing epidemics of small-pox in recent times. Medical men themselves differed in opinion as to the efficacy of vaccination as much as lawyers differed about Acts of Parliaments. Nothing would satisfy the great majority of the population but the total abolition of compulsory vaccination.

Mr. Chaplin then addressed the House. With regard to the cost of the scheme he said it would be borne in precisely the same way as that of the present system of vaccination was borne. The notification would be given under the Notification of Diseases Act, which was compulsory in the metropolis at the present time. Though that Act was optional in other districts of the country, it was practically in force in respect of 28,000,000 of persons out of a population of 29,000,000. With regard to the compulsory provision of hospitals for isolation, he showed that under the Public Health Act the local authorities could provide hospitals if their representatives desired, and county councils at the present time had an absolute power to form districts and to require the provisions of the Isolation Hospitals Act to be put in force subject to certain restrictions. It was said that the cost of vaccination would be increased. The remuneration of vaccination officers and public vaccinators was subject at present, and would be in future, to the approval of the Local Government Board. Their duties would be increased to some extent no doubt, and he recognised that there must be some alteration in their remuneration. What the Government proposed was that both classes of officers should be remunerated in future by two methods. First, by a payment based on the number of births to cover all their general duties; and, second, by a payment in each case for successful vaccination. To encourage this the Government thought that the fee for the last-named duty should be higher than the fee for the former. The amount of the fees was a matter for arrangement between the local authorities and the officers who were employed, but it was subject in all cases to alteration and approval by the Local Government Board. In addition to this, under the system of awards which existed at present and which would be continued in the future, there would be the award which was certified at the present time by the Local Government Board and which was paid by county councils, and which was not to exceed under the existing law 1s. in the case of each successful vaccination. The amount raised by public rates in the country at the present time was practically about £35,000,000; the whole cost of vaccination expenses at present was £78,000 a year. If the cost of vaccination was doubled, which was extremely unlikely, it would mean an increase of less than half a farthing in the pound on the rateable value, and if trebled less than a farthing. The efficacy of vaccination for the prevention and mitigation of small-pox appeared to him to have been demonstrated by the experience of the world. Dealing with the procedure to be adopted under the new regulations, he indicated that the registrar of births and deaths at the time of the birth of a child gave information to the parents as to their duties in respect of vaccination. At the same time the registrar gave a list of births to the vaccination officer. It then became the duty of the parent under the Bill to have the child vaccinated within twelve months from that time. The parent might employ either a private or a public vaccinator, but whichever officer was employed it would be his duty, if he vaccinated successfully, to send a certificate to that effect to the vaccination officer who had already the list of births, and by comparing that list with the certificates which he received he would be able to ascertain at once who had and who had not been vaccinated. If a parent had employed neither officer by the end of nine months, then it became the duty of the public vaccinator to call at the residence and offer to vaccinate the child, giving due notice of the time at which he would do so. At the end of twelve months, the public vaccinator having made this offer, if the child remained unvaccinated the parent would become liable to prosecution, the vaccination officer giving notice before taking proceedings. Under the powers which the Board already possessed they proposed in future to make it the duty of the vaccination officer to institute the necessary proceedings. That would be a change in the present practice with regard to vaccination to which he, for one, attached very considerable importance. It would also be the duty of the vaccination officer to take proceedings for enforcement of the second penalty if it should be necessary for him to act. Something had been said about the difficulty in connexion with removals in consequence of the age being postponed to twelve months. It would be part of the vaccination officer's duty to make every inquiry as to those removals and to ascertain the district into which the removal had been made. While wishful to include provisions for revaccination in the Bill he was still more anxious to get the measure passed into law this Session. He had some fears that if at the outset he overloaded the Bill with an unnecessary number of new provisions he might fail in his primary object. To the importance of the proposal that children should be inspected when they entered school so that they might be vaccinated if they had escaped vaccination in their earlier years he was quite alive, and with the support of the hon. Member (Sir Walter Foster) it might be found possible to introduce into the Bill an amendment on this point. To the adoption of the hon. Member's suggestion with respect to vaccination by private practitioners there were practical obstacles. He did not understand why a burden which had hitherto been borne cheerfully by private individuals should be imposed upon the rates. Then the work of all public vaccinators was carried out under strict regulations and if they were disregarded the officer could be dismissed. Over private practitioners, who numbered 21,000, similar control could not be exercised. The hon. Member had urged him not to do away altogether with stational vaccination, pointing out that at times it would be of the greatest possible use. The subject was well worth considering; but he might explain that stational vaccination was only to be abandoned in a certain sense. It would cease to be

compulsory and children would no longer be required to attend in order that lymph might be transferred from their arms to those of others; but there was no intention to prevent guardians from having recourse to stational vaccination if they should think fit to do so. It was probable that in populous places where serious outbreaks of small-pox occurred stational vaccination would still be resorted to. He came now to the question of repeated penalties, which had caused such acute differences of opinion. Upon this subject there appeared to be much misapprehension in the minds of large sections of the public and even in the minds of people who ought to know better. It had been stated constantly that anybody by paying a trivial fine in one case could purchase exemption thereafter from the operation of the Bill. That was quite a mistake. It would be for the magistrates to determine whether the fines should be trumpery or not, but all defaulters would be liable under the Bill to two prosecutions. Under the 29th section of the Act of 1867 a parent who neglected to vaccinate a child before twelve months would be liable to a penalty, and under section 31 if a registrar or officer of a board of guardians informed a magistrate that he had reason to believe that any child in the union under fourteen years of age had not been successfully vaccinated the magistrate could summon the parent of the child and could make an order directing vaccination within a certain time. If the order was not obeyed the parent became liable to a penalty and at present an order of the kind could be repeated again and again *ad infinitum*. Under the present Bill defaulters would be liable to two prosecutions and two penalties, but the unlimited repetition of orders directing the vaccination of a child would be prohibited. He knew that this proposal to repeal the law permitting the imposition of repeated penalties had met with a great amount of disapproval and if the system which had hitherto prevailed had been effective in securing the vaccination of children whose parents objected to it there would no doubt be a great deal to be said for the retention of the present state of things. Too many records, however, showed that, far from succeeding in promoting vaccination, the system of imposing repeated penalties had rather an opposite effect. One result of the system had been to make martyrs of many misguided but no doubt well-meaning people, and so to create prejudice against the whole practice of vaccination. Whenever this question of repeated penalties had been made the subject of public inquiry a modification of the law had been unanimously recommended. Having given the question the best consideration in his power he had come to the conclusion that the balance of argument, and certainly the balance of authority, was in favour of the proposal he had made. Complaint had been made that the Bill did not accept the other recommendations of the Royal Commission. The hon. Member for Ilkeston (Sir Walter Foster) said the Royal Commission had killed compulsory vaccination, that one-fifth of the local authorities decline to carry it out, and that therefore it would be better to accept that position. He was, however, not without hope that with an improved and amended Bill such as this, with conditions entirely altered, with many of the gravest objections to vaccination removed, and with greater facilities for carrying it out being offered in the future, much of the opposition to vaccination might, and probably would, die out, and that it would be found that the local authorities would be prepared to enforce the law much more readily than in the past. In the great majority of cases in which people neglected vaccination they did so from indolence or carelessness rather than from any rooted objection to the practice. All such cases would be met and provided for by the Bill. But there was an active and powerful body of men in the country who desired the total repeal of the vaccination law and who were ceaselessly working to procure its abolition. With their powerful organisation, with their ceaseless and restless energy, nothing in the world would be simpler than to arrange for conscientious objections to be presented by the thousand, and he was afraid that if he accepted the proposal of the hon. Member for Ilkeston they would soon see the vaccination law become a dead letter in a number of districts. He was as strongly convinced as any Member in the House that vaccination was an absolute necessity in the interest of the community as a whole and so long as he was responsible in the matter nothing would induce him to sanction anything of the kind. The best mode of enforcing the law might, he admitted, remain to be proved in the future. He believed honestly that the course he had adopted was the right one, but if it failed—and he did not believe it would—he should not hesitate to come to Parliament again and again, if necessary, for any additional powers that might be needed to thoroughly enforce vaccination throughout the country. At the same time he thought he had some right to hope that no such steps would be required. In this Bill the Government had done their utmost to remove, on the one hand, every legitimate grievance and every plausible objection that could be raised to the practice of vaccination, while, on the other hand, they had sought to provide, especially for the poorer classes—though he altogether denied that this was a question affecting only the poorer classes—facilities for vaccination which had never been enjoyed before and he asked the House to approve what they had done.

Mr. Pickersgill, opposing the Bill, prophesied for glycerinated calf lymph absolute failure and took exception to Mr. Chaplin having made arrangements with the Institute of Preventive Medicine for its supply. Than this institute, he said, there was no body more unpopular and more distrusted by the people of London. He did not think that the medical profession would thank either Sir Walter Foster or Sir William Priestley for the references they made to members of the profession. The former charged members of his own profession with making sham operations with pretending to vaccinate, and after so pretending giving a certificate of vaccination. Did not that open up a rather alarming prospect to many of them? Then Sir William Priestley had told them that he stood aghast at the risks run in vaccination in the days of his youth. Yes; and in the days of Sir William Priestley's youth vaccination was supported in this House by just the same arguments as it was now supported These statements made by distinguished members of the medical profession would be taken to heart by the country and would make it all the more determined that the system of compulsory vaccination should no longer be continued.

Mr. Monk said he wished to repeat his denial of the statement that the drinking water of Gloucester was taken from the Severn. It was taken from the reservoirs and was a most admirable supply. Indeed, there was no city in England which was now better supplied with water. As to the drainage of Gloucester it would compare favourably with any city or town in the country. As to the epidemic the mortality was certainly great, but while it was less than 10 per cent. among vaccinated people it was 40·8 per cent. among unvaccinated.

On the motion of Mr. Logan the debate was adjourned.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BELBEN, F., M.B. Cantab., F.R.C.S., L.R.C.P. Lond., has been appointed Resident Surgical Officer to the Hull Royal Infirmary.

BOX, STANLEY, M.B. Lond., M.R.C.S., L.R.C.P., D.P.H., has been appointed Resident Assistant Surgeon to the Western General Dispensary, Marylebone-road, London.

CODD, J. ALFRED, M.D., B.Sc. Lond., has been appointed Honorary Assistant Physician to the Wolverhampton and Staffordshire General Hospital, Wolverhampton.

DAVIES, W. J. E., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Resident Medical Officer to the Chelsea Infirmary.

DIXSON, C. F. L., M.D. Durh., M.R.C.S., has been appoined Honorary Anæsthetist to the Brentford Cottage Hospital and Dispensary.

GILMOUR, R. W., M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed fifth Medical Officer and Pathologist to the Waduley Asylum.

GOSTLING, T. P., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Surgeon to the Worcester Infirmary.

HODGSON, G. G., M.R.C.S., has been appointed Honorary Assistant Surgeon to the Sussex Eye Hospital, Brighton.

HITCHINS, F. C., M.R.C.S. Eng., L.R.C.P., has been appointed House Surgeon to the Stamford and Rutland Infirmary, Stamford.

IONIDES, T. H., M.B. Lond., B.S., F.R.C.S., has been appointed Honorary Assistant Surgeon to the Sussex Eye Hospital, Brighton.

JOHNSTON, J. SOMERVILLE, L.K.Q.C.P., L.R.C.S. Irel., has been appointed Visiting Surgeon to the St. Nicholas Industrial Schools, Manor Park, vice P. C. Boyd, resigned.

JOHNSTONE, THOMAS, M.D. Edin., M.R.C.P. Lond., has been re-appointed Medical Officer of Health to the Ilkley Urban District Council.

KINSELLA, J. J., M.B., B.Ch. Irel., has been appointed Medical Officer to the Workhouse of the Edenderry Poor-law Union.

MACGREGOR, ALEXANDER, M.D. Aberd., M.R.C.P. Lond., has been appointed Physician to the Westminster General Infirmary.

MACKAY, H., L.S.A. Lond., has been appointed Medical Officer for the South-East sanitary district the Sheffield Union, vice C. E. Strickland, resigned.

MACMUNN, C. A., M.D. Dubl., L.R.C.S. Irel., has been appointed Honorary Physician to the Wolverhampton and Staffordshire General Hospital, Wolverhampton.

MOLESWORTH, F. H., M.B., B.C. Cantab., has been appointed Assistant House Surgeon to the Stockport Infirmary.

PRICE, F. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Great Indian Peninsula Railway.

ROUTLEDGE, C. L., L.D.S., R.C.S. Edin., has been appointed to the Senior Staff of the Newcastle-on-Tyne Dental Hospital and School.

ROWLANDS, D. R., M.B., C.M. Edin., has been appointed House Physician to the Swansea Hospital.

SHELLY, C. E., M.D. Camb., M.R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician by the Hertford and Ware Joint Hospital Board.

TASKER-EVANS, J. T., M.D. Aberd., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Physician by the Hertford and Ware Joint Hospital Board.

TAYLOR, H. H., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Surgeon to the Sussex Eye Hospital, Brighton.

VERDON-ROE, S., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to the Radcliffe Infirmary, Oxford.

WARD, J. P. S., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Plymouth Public Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Surgical Officer. Salary £50, with board, washing, and attendance.

BIRMINGHAM CITY ASYLUM.—Clinical Assistant. Board, lodging, and washing provided.

BOROUGH OF MIDDLESBROUGH.—Medical Officer of Health. Salary £350 per annum, payable monthly. Applications to the Town Clerk, Middlesbrough.

CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY, Wakefield.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

EAST SUFFOLK AND IPSWICH HOSPITAL, Thoro'fare, Ipswich.—Senior House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

GENERAL INFIRMARY, Gloucester, and GLOUCESTERSHIRE EYE INSTITUTION, Gloucester.—Assistant Surgeon.

HOSPITAL AND DISPENSARY, Newark-upon-Trent.—House Surgeon, unmarried. Salary £80 per annum, with board and lodging in the hospital. Will be required to do the dispensing for the hospital and free and provident dispensaries, for which an additional salary of £40 is paid.

HOSPITAL OF ST. FRANCIS, 145, New Kent-road, London.—Honorary Assistant Surgeon, two Honorary Assistant Physicians, and Anæsthetist.

KILBURN, MAIDA-VALE, AND ST. JOHN'S-WOOD GENERAL DISPENSARY.—Two vacancies on the Board of the Hon. Medical Staff. Applications to the Secretary, 13, Kilburn-park-road, N.W.

LONDON THROAT HOSPITAL, Great Portland-street.—House Surgeon (non-resident), for six months, Salary £25.

MIDDLESBROUGH COUNTY BOROUGH ASYLUM, Cleveland, Yorkshire.—Assistant Medical Officer, single. Salary £100 per annum, with furnished apartments, board, washing, and attendance.

NORFOLK AND NORWICH HOSPITAL, Norwich.—Honorary Physician.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Resident Medical Officer and Assistant Resident Medical Officer, each for six months. Salary at the rate of £50 per annum, attached to the senior post.

ROYAL ALBERT HOSPITAL, Devonport.—Resident Medical Officer for two years, unmarried. Salary £100 per annum, with board and lodging.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor, Isle of Wight.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging in the hospital. Applications to the Board of Management, London Office, 34, Craven-street, Charing-cross, W.C.

ST. PANCRAS AND NORTHERN DISPENSARY, 126, Euston-road, London.—Resident Medical Officer, unmarried. Salary £105, with residence and attendance. Applications to the Honorary Secretary, Mr. H. P. Bodkin, 23, Gordon-street, Gordon-square, W.C.

ST. MARY'S HOSPITAL, Paddington, London.—Honorary Radiographer.

SEAMEN'S HOSPITAL SOCIETY (Dreadnought), Greenwich, S.E.—House Surgeon for the Dreadnought Hospital, Greenwich. Salary £50 per annum, with board and residence. Also Junior House Surgeon for the Branch Hospital, Royal Albert Dock, E. Salary £50 per annum, with board and residence. Applications to the Secretary, Greenwich.

SUFFOLK COUNTY ASYLUM.—Second Assistant Medical Officer, for three years, unmarried. Salary £100 a year, with board, lodging, washing, and attendance. Applications to the Medical Superintendent, Melton, Suffolk.

THE GUEST HOSPITAL, Dudley.—Resident Assistant House Surgeon, for six months. Salary at the rate of £20 per annum, with board, lodging, and washing in the hospital.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—House Physician, for six months, unmarried. Salary £20, with board and residence in the hospital. Also House Surgeon to out-patients (non-resident), for six months. Salary 25 guineas.

TUNBRIDGE WELLS EYE AND EAR HOSPITAL.—Lady House Surgeon. Salary £60, and board and lodgings. Applications to the Honorary Secretary, 3, the Pantiles, Tunbridge Wells.

WEST DERBY UNION.—Resident Assistant Medical Officer at the Mill-road Infirmary, for one year. Salary £100 per annum, subject to statutory deduction, with board, lodging, and washing. Applications to the Clerk to the Guardians, Brougham-terrace, Liverpool.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL INFIRMARY, Wolverhampton.—House Physician, who will be required to act as Medical Registrar, Pathologist, and Anæsthetist, for one year. Salary £100 a year, with board, lodgings, and washing.

YORK DISPENSARY.—Resident Medical Officer to visit and attend (including midwifery), the sick poor at their own homes, unmarried. Salary £150 a year, with furnished apartments, coals, and gas. Applications to W. Draper, Esq., De Grey House, York.

Births, Marriages, and Deaths.

BIRTHS.

BUTLER.—On Easter Monday, at Westfield House, Flaxton, Yorkshire, the wife of W. Barber Butler, M.R.C.S., of a daughter.

GODFREY.—On April 13th, at Lichfield-grove, Finchley, N., the wife of T. H. Godfrey, M.B., of a son.

HAGUE.—On April 13th, at Kingston House, Camberwell, the wife of S. Hague, M.D. St. And., of a daughter.

JACKSON.—On April 15th, at Alnwick, the wife of G. Scott Jackson, M.D., of a daughter.

MOLSON.—On April 13th, at Rainsford House, Chelmsford, the wife of J. Bladale Molson, M.B., B.C. Cantab., of a daughter.

NEWINGTON.—On April 11th, at The Grange, Edenbridge, Kent, the wife of C. W. H. Newington, M.R.C.S., L.R.C.P., of a son.

WALLIS.—On April 15th, at Roman-road, Bow, E., the wife of Sidney Seymour Wallis, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

BLACKER—HARVEY.—On April 13th, at St. Paul's Church, Clifton, by the Rev. W. H. P. Harvey, M.A., Vicar of St. John's Church, Chipping Sodbury (brother of the bride), assisted by the Ven. A. C. Ainslie, LL.D., Archdeacon of Taunton, and the Rev. Canon Mather, M.A., Vicar of St. Paul's, Ernest Blacker, M.D., M.R.C.S., L.R.C.P., of Southampton, son of the late Dr. Blacker, of Midsomer Norton, to Edith Emilie, youngest daughter of the late Rev. George Ludford Harvey, M.A., Rector of Yate, Gloucestershire, and granddaughter of the late Sir Ludford Harvey, many years senior surgeon of St. Bartholomew's Hospital, London.

BOON—WOOD.—On April 19th, at Sherborne Abbey, John Goodisson Boon, L.R.C.P. and L.R.C.S. Irel., Broseley, Shropshire, to Olive Dunbar, only daughter of the Rev. Alexander Wood, Sherborne.

EVANS—HOWSE.—On April 13th, at the Church of All Hallows, London-wall, E.C., by the rector, the Rev. S. J. Stone, cousin of the bridegroom, Harold Ward Evans, M.R.C.S., L.R.C.P., of Littleport, Cambs., younger son of the late Francis Stone Evans, Esq., M.A., late Principal of the Presidency College of Madras, to Hilda Mabel, fourth daughter of the late Alfred Howse, Esq., M.R.C.S.

FRY—ROSS.—On April 13th, at St. Barnabas's Church, Middlesbrough, W. L. Fry, M.B. Oxon., third son of C. Rutter Fry, of Darlington, to Bertha Mary, third daughter of the late John Ross, formerly of Feethams, Darlington.

GRIFFITH—TALBOT.—On April 12th, at Mill Hill Chapel, Leeds, Thomas Wardrop Griffith, M.D., youngest son of the late Charles Fox Griffith, Aberdeen, to Louisa Talbot, younger daughter of Grosvenor Talbot, Burley, Leeds.

HAWKES—COGHILL.—On April 14th, at the Parish Church, Ventnor, by the Rev. A. L. B. Peile, M.A., Master of St. Catherine's and Chaplain to the Queen, assisted by Rev. H. D. Macnamara, Rector of St. James, Garlickhithe, E.C., Priest in Ordinary to the Queen, Rev. A. Alloway, Chaplain to the Ventnor Hospital, and Rev. G. P. Bassett Karry, Vicar of Ventnor, Lewis Arthur Hawkes, M.D., to Mary Stuart Coghill, L.R.C.P., L.R.C.S., eldest daughter of Dr. and Mrs. Coghill, of St. Catherine's House, Ventnor, I.W.

HILL—BACHLER.—On April 12th, at St. Jude's Church, Southsea, Reginald Augustus Lowder Hill, M.R.C.S. Eng. and L.R.C.P. Lond., of Wimbledon, to Maud Mary Ann, only daughter of Leonard Bachler, Esq., Inspector of Machinery, R.N.

LIGHTBODY—MEYLER.—On April 14th, at Shepperton Church, by the Rev. C. F. Chorley, Vicar of Mossley, assisted by the Rev. C. E. Littledale, Rector of Shepperton, John Henry Lightbody, M.D., of Wybunbury, Cheshire, eldest son of the late John Lightbody, of Liverpool, to Constance Helen, second daughter of the late T. H. Meyler, of Taunton, Somerset.

NEWTON—CARTER.—On April 14th, at St. Clement's, Bournemouth, Henry William Newton, M.R.C.S., L.R.C.P., D.P.H., of Chelmsford, to Edith Mabel Carter, elder daughter of the late Mr. E. Hunt Carter, of Chelmsford.

RANSOM—FOWLER.—On April 19th, at Christ Church, Cinder-hill, Nottingham, William Bramwell Ransom, M.D., eldest son of Dr. W. H. Ransom, F.R.S., to Edith Mary Isabel, eldest daughter of George Fowler, Esq., M. Inst. C.E., of Basford Hall, Nottingham.

DEATH.

HOWLETT.—On April 15th, at Lugano, Gerard Dalziel Howlett, M.R.C.S., L.R.C.P., second and much-loved son of Richard and Alice Howlett, aged 24 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.).

WEDNESDAY (27th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.).

THURSDAY (28th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.).

FRIDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (30th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.) St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (26th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Dr. T. R. Bradshaw (communicated by Dr. Lauder Brunton): A Case of Albumosuria in which the Albumose was Spontaneously Precipitated.—Dr. S. West: Intrapleural Tension.

WEDNESDAY (27th).—HUNTERIAN SOCIETY.—8.30 P.M. Dr. F. Fox: Observations on Crisis.—Mr. H. H. Tubby: Coxa Vara.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Communication:—Dr. Wm. Bain (Harrogate): The Action of certain Drugs and Mineral Waters on the Secretion and Composition of Human Bile—an experimental investigation. Paper:—Dr. E. Hobhouse (Brighton): Gout and Rheumatism in Relation to the Sea-shore and Salt-water Baths.

THURSDAY (28th).—HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, W.).—8.30 P.M. Mr. P. J. Freyer: My Latest Series of 100 Operations for Stone in the Bladder with Practical Remarks thereon.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—5 P.M. Cases will be shown.

FRIDAY (29th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Clinical Evening. The following cases will be shown:—Mr. F. Eve: Cases of Transplantation of Tendon for Infantile Paralysis.—Dr. W. Pasteur: Case of Graves's Disease in which Bradycardia has supervened.—Mr. A. E. Garrod: Cases illustrating the Association of Congenital Heart Disease with the Mongol type of Idiocy.—Mr. W. Spencer: Case of Acute Gangrenous Appendicitis in a Boy, Removal of Appendix twenty-six hours after onset (with specimen).—Dr. C. E. Beevor: Case of Amyotrophic Lateral Sclerosis with Jaw Clonus.—Dr. H. D. Rolleston: Hemiplegia after Typhoid Fever.—Dr. H. D. Rolleston: Osteitis Deformans in a Woman. And other cases. Patients will be in attendance at 8 P.M.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (Medical Society's Rooms, 11, Chandos-st., Cavendish-sq., W.).—3 P.M. Laryngological Section. Cases will be shown by Dr. B. Baron, Dr. Tresilian, Mr. W. Wingrave, Dr. E. S. Young, and Mr. St. G. Reid. Papers will by read by Dr. B. Kelly and Dr. Tresilian. 5 P.M. Otological Section. Cases will be shown by Dr. D. Grant, Mr. W. Wingrave, and Dr. G. Stoker.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

MONDAY (25th).—THE SANITARY INSTITUTE (Parkes Museum Margaret-street, W.).—8 P.M. Mr. C. Jones: Scavenging, Disposal of House Refuse.

THURSDAY (28th).—THE SANITARY INSTITUTE (Parkes Museum Margaret-street, W.).—8 P.M. Prof. H. Robinson: Sewerage and Sewage Disposal.

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Lantern Demonstration to Senior Students—Heart Disease.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

UNDESIRABLE PUBLICITY.

THE Royal Halifax Infirmary authorities have recently put an advertisement in the local papers giving notice of some arrangements made in connexion with the special department for diseases of the ear, eye, nose, and throat. In this advertisement the name of the medical man in charge of this department is mentioned, with an intimation that he confines his practice to diseases of the eye, ear, nose, and throat only. There is also a laudatory editorial paragraph about the same gentleman. We do not suppose for a moment that the medical man in question authorised either advertisement or paragraph in any way, but the infirmary authorities should know better.

LONDON DRAINS.

To the Editors of THE LANCET.

SIRS,—That it is exceptional for sewer gas to contain many micro-organisms is a discovery for which sanitarians may well be grateful. Reactionaries are apt to say to us, "If this gas is so highly injurious, why are we not all dead men?" We can now distinguish and define. There are probably tens of thousands of houses in London into which gas from the drains easily escapes, but until a casual pathogenic "germ-cloud" escapes with it there is no specific disease. Nevertheless, in the inmates of these houses some (often unrecognised) loss of energy, degrees of anæmia, variation of temper and of intellect will always be found. It is necessary to arrive if possible at complete clearness upon this matter. Quite recently an architect, an advocate of the strictest sanitary measures, told the writer with an evident tone of perplexity and puzzle that he had examined a house in which a man had lived for twenty years, that during all that time sewage had accumulated in the soil beneath the house running over from a cesspool, and that yet the man had never been ill. But I knew the man and that it might be equally true to say that he had never been well or at his best. It is the brain cells which are most readily injured by poisons and by anæmia and want of oxygen in the blood. In this case no specific microbes from a common sewer could find their way into the drains and cesspool of the house; the

ground was ready but the seed was not sown. Hence the immunity which had to some extent shaken the belief of my friend in the reality of the danger of sewer gas. He was expecting an impossible result, as though he had looked for wheat in a field merely because the soil had been enriched. The germs of every specific disease must enter and exist in the sewers. Their escape is an accident which may happen anywhere. No house into which there is a leak is safe; on the other hand any house however faulty may escape. This latter fact has caused a state of doubt or imperfect belief even in the minds of members of sanitary committees as to the degree of danger to be encountered, and has led to a corresponding want of firmness and resolution in their actions, and this simply because it appeared that much worse results ought uniformly to occur when house drains were defective than actually did occur. An explanation based on accurate observations which seems likely to remove this difficulty is therefore highly acceptable.

I am, Sirs, yours faithfully,

April 11th, 1898. T. C.

A HINT.

WE extract the following advertisement from the *Bazaar* of March 28th, 1898:—

MEDICAL.—Wanted, standard homœopathic books and drugs. Hints gratefully accepted. Vicar, B——, D——.

We are happy to give "Vicar" a hint and hope he may be as grateful for it as he promises to be in the advertisement. We might multiply hints, but one hint will cover all the ground. It is that he should not interfere with what he does not understand. Suppose he drugs a person and that person dies, "Vicar" cannot sign a death certificate—at least not a valid one. In that case the coroner at the ensuing inquest would certainly make strong remarks upon "Vicar's" unfortunate position, and "Vicar" might even find himself nearer a trial for manslaughter than would be seemly in one of his cloth.

INFECTION IN THE STREET.

To the Editors of THE LANCET.

SIRS,—Through the medium of your widely read columns I beg to call the attention of the medical world to what I believe to be a source of infection and I write in the hope that this letter may be the means of eliciting competent opinion on the subject. It appears to me that the laying down of straw in the public streets is a practice which, limited as it may be, is prejudicial to health for several reasons and should not be resorted to save in extreme cases. In the first place, it is dirty, as the portion of the road thus covered is left unattended to by the scavengers during periods of various length. The drains also probably suffer in consequence. Moreover, the straw mixing with the natural deposits and accumulations of the road and being in a state of constant disturbance and decay must originate and diffuse dangerous germs. These would, I suppose, vary in quantity with the condition of the straw, the nature of the pavement, and the weather, but the difference would be only in degree. The bruised straw absorbs rain and other moisture and when upon this warm weather prevails some poisonous germination no doubt takes place. When in a dry condition the straw in its constant disturbance and reduction gives off a cloud of unwholesome particles which affect the surrounding atmosphere. The pollution is spread abroad, and in the case of weak or sick people this air, charged with the miasma of decaying vegetable matter, must be highly injurious. It would seem therefore that what invalids gain in one way from the use of straw they may lose in another. Admitting the necessity for the use of straw in certain cases we must yet hope that in view of its creating and diffusing infection to the prejudice of the public health its use may be restricted as much as possible.

I am, Sirs, yours faithfully,

April 18th, 1898. P.

A NOVELTY IN SHOES.

ORDINARY boots and shoes made of leather impervious to air and moisture encourage perspiration of the feet and the formation of products of decomposition. To remedy this defect Dr. Spener of Berlin recommends in the *Deutsche Medicinische Wochenschrift* of April 7th that boots and shoes should be lined with canvas treated by a process which renders it waterproof without loss of porosity. This canvas is of the same colour as the upper leather, which latter is perforated with holes arranged in any kind of tasteful pattern, the margin where it joins the sole being left without perforations for a width of about half an inch. In this way the shoe is ventilated and the perspiration escapes as vapour, while at the same time the foot is completely protected from damp due to rain or other causes, as well as from dust or mud. To prevent the perforations becoming stopped up by blacking or varnish the leather should be well brushed with a dry brush. Shoes made in this way were worn by Dr. Spener during a seven weeks' journey in Russia in the summer of 1897 and gave him entire satisfaction.

THE EYESIGHT OF CIVIL SERVICE CANDIDATES.

To the Editors of THE LANCET.

SIRS,—Can any of your readers tell me where I can ascertain the amount of defect of refraction permissible to candidates for the Civil Service?

I am, Sirs, yours faithfully,

April 19th, 1898. ENQUIRER.

"AN OBSTINATE CASE OF HERPES."

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Blake's query in THE LANCET of April 9th, p. 1035, "An Obstinate Case of Herpes," I beg to say that in my experience herpes genitalis, if not symptomatic of urethral discharge or stricture, is usually due to the decomposition of the smegma præputiale. Ointments mix with the latter and share in the decomposition to which the smegma is so liable, hence I think there is a contra-indication against the use of fatty substances. In my opinion scrupulous cleanliness is the most effective preventive against the recurrence of this troublesome complaint. I consider hot alcoholic lotions, as eau de Cologne or brandy in water, quite sufficient. But as the treatment is usually more steadily persevered in when a medicinal lotion is given I am in the habit of prescribing the following lotion: boric acid, 2 dr.; absolute alcohol, 1 oz.; and rose-water to 6 oz. This is to be diluted with equal parts of *boiling* water and is to be used as a lotion several times a day. A dusting powder containing dermatol and calomel assists the treatment. I usually prescribe the following dusting powder: calomel, 20 gr.; dermatol, 30 gr.; and bismuth subnitrate, 1 dr. This treatment has to be carried out regularly for from four to six weeks and then to be repeated about once or twice a week. If every other remedy fails the nitrate of silver pencil usually effects a cure.

I am, Sirs, yours faithfully,

H. OPPENHEIMER, M.D. Heidl., M.R.C.P. Lond.

Adamson-road, Swiss Cottage, N.W., April 11th, 1898.

F.R.C.S.—It is undoubtedly the duty of the medical man to warn the relatives in the matter of a patient who exhibits suicidal tendencies. Should they refuse to take action it might conceivably be his duty to take further action or intimate such a step to the relatives, but no general rule can be laid down, for the special circumstances of each case must be taken into consideration. There is no question of "privilege" at all.

L.S.A. has acted rightly, but we cannot agree with him that any purpose would be served by printing his letter and giving public approval to the course that he has taken. Surely the medical profession—the younger members every whit as much as their seniors—know that under such circumstances to procure an abortion is a crime. We think that to insist upon the point would be impertinent because unnecessary.

L.R.C.P., L.R.C.S., &c.—The matter is one for mutual arrangement. We understand our correspondent to be an employé and not a partner, in which case it seems to us the fees belong to the principal and he can make no legal claim. But if he actually earns most of the fees there can be no objection to his asking to participate in them.

W. H. B. (Bradford).—We never recommend individual practitioners, specialist or other. The medical man in attendance on the case can give advice as to the seeking a consultant's opinion and there is no need whatever to look beyond the two large cities named for adequate medical assistance.

Monkshood—Our correspondent will find the precise information he asks for in THE LANCET of July 15th, 1895, pp. 76, 77, and 78.

Observer's is an ingenious speculation, but no more.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Isle of Wight Observer, Lancaster Standard, Callander Advertiser, Bradford Daily Argus, Norfolk Daily Standard, Brisbane Courier, Kentish Express, North British Mail, Devon Gazette, Times of India, Pioneer Mail, South Wales Daily News, Dundee Advertiser, Glasgow Herald, Liverpool Daily Post, Melbourne Age, Dorking Advertiser, Sheffield Telegraph, Manchester Guardian, Birmingham Post, Builder, Sussex Daily News, Keighley News, Yorkshire Post, Huntingdonshire Post, Newbury Express, Kettering Leader and Observer, Worcester Echo, North Wilts Herald, Bristol Mercury, South Western Star, Barnsley Independent, Essex Telegraph, Accrington Observer, Dalton Advertiser, Leeds Mercury, Cheshire Observer, New Ross Reporter, Midland Free Press, Architect, Scotsman, Fairplay, Mining Journal, Reading Mercury, City Press, Hertfordshire Mercury, Local Government Chronicle, Surrey Advertiser, Local Government Journal, Weekly Free Press and Aberdeen Herald, St. Bartholomew's Hospital Journal, Lincoln Mercury, Auckland Chronicle, Forres Gazette, Hobart Mercury, Ceylon Observer, Banffshire Advertiser, Falkirk Herald, Clifton Chronicle, St. Andrew's Citizen, Boston Independent, Nairnshire Telegraph, Sunderland Daily Echo, Evening Chronicle (Newcastle-on-Tyne), High Peak News, Berkshire Chronicle, Suffolk Chronicle, Montgomeryshire Express, Hornc stle News, Pembroke City Guardian, Munster Express, Cromer Post, West Middlesex Herald, New Ross Reporter, Guernsey Mail, Citizen, &c., &c.**

Communications, Letters, &c., have been received from—

A.—Dr. J. Althaus, Lond.; Messrs. Allen and Hanburys, Lond.; Mons. J. Astier, Paris; Dr. R. Y. Aitken, Blackburn.

B.—Mr. L. A. Bidwell, Lond.; Mrs. E. W. Bailie, Soochow, China; Messrs. A. and C. Black, Lond.; Dr. T. S. Brodie, Houston; Mr. T. Blackett, Lond.; Dr. A. B. Boyd, Richmond, N.Z.; Mr. S. Boyd, Lond.; Dr. M. M. Bowlan, Lond.; Mr. J. de C. Boscawen, Truro; Mr. J. P. Bush, Clifton; Mr. P. H. Boyden, Thorpe Hamlet; Messrs. Blondeau et Cie, Lond.; Mr. G. Booth, Woodbridge; Mr. H. N. Bushby, Lond.; Birmingham City Asylum, Medical Superintendent of; Birmingham and Midland Free Hospital, Secretary of.

C.—Mr. S. N. Corlett, Lond.; Mr. R. Cuffe, Woodhall Spa; Clayton Hospital, Wakefield, Hon. Secretary of; Mr. E. J. Carter, Tunbridge Wells; Dr. T. S. Carrington, Marsovan, Turkey; Dr. J. Clarke, Gurdaspur, Punjab, India; Dr. T. Churton, Leeds; Dr. H. H. Crook, Margate; Mr. J. D. Campbell, Lond.; Dr. W. Collingridge, Lond.; Messrs. Cassell and Co., Lond.; Chelsea Hospital for Women, Lond., Secretary of; Messrs. J. and A. Churchill, Lond.; Mr. J. B. Cameron, Lond.

D.—Dr. W. Dickson, Leicester; Messrs. Domeier and Co., Lond.; Messrs. A. De St. Dalmas and Co., Leicester; Mr. E. Drake, Lond.; Messrs. W. Dawson and Son, Lond.; Messrs. S. Deacon and Co., Lond.

E.—Surgeon-Captain H. M. Earle, Peshawur, India; Messrs. Evans, Gadd and Co., Exeter; Elberfeld Farbenfabriken Co., Lond.; East Suffolk Hospital, Secretary of.

F.—Mr. R. J. Farman, Lond.; Messrs. Ferris and Co., Bristol; Foreign Press Office, Paris; Messrs. Fairchild Bros. and Foster, Lond.; Fellows Manufacturing Co., Lond.; Dr. F. D. Fisher, Bury St. Edmunds; F. C., Lond.

G.—Dr. G. M. Gould, Philadelphia, U.S.A.; Glasgow University, Secretary of; Dr. L. G. Guthrie, Lond.; Dr. E. Goddard, Lond.; Mr. L. M. Griffiths, Bristol; Mr. A. E. Gilbert, Newcastle-on-Tyne; Grantham Town Council, Clerk of; Messrs. Griffin and Co., Lond.

H.—Mr. E. C. Hodgson, Dublin; Dr. F. W. H. Hutchison, Finchingfield; Mr. F. Hobday, Lond.; Harveian Society, Hon. Secretary of; Dr. T. Harris, Manchester; Rev. A. P. Hockin, St. Margaret's-at-Cliffe; Mr. C. H. Huish, Lond.; Mr. J. Heywood, Manchester.

J.—Mr. N. B. Jenkins, Knoxville, U.S.A.; Jeyes' Sanitary Compounds Co., Lond.

K.—Dr. H. Kenwood, Lond.; Dr. A. Kinsey-Morgan, Bournemouth; Dr. N. Kerr, Lond.; Mr. E. Knight, Lond.; Kilburn Dispensary, Lond., Secretary of.

L.—Mr. H. K. Lewis, Lond.; Leamington Corporation, Town Clerk of; Messrs. Lee and Martin, Birmingham; Liverpool Royal Infirmary, Secretary of; Mr. W. M. Laurin, Lond.; Mons. H. Le Soudier, Paris.

M.—Dr. C. MacDonnell, Dundalk; Mr. J. Milne, Lond.; Messrs. J. and C. Mort, Stafford; M.D., London; Messrs. Moseley and Co., Sheffield: Mr. Martin, Darlington; Mr. W. Marriott, Lond.

N.—Newark-on-Trent Hospital, Secretary of; Mr. A. W. Nuthall, Lond.; National Telephone Co., Lond., District Manager of; Norfolk and Norwich Hospital, Norwich, Secretary of; Numero, Lond.

O.—Ogden's, Ltd., Liverpool; O. A., Lond.; Mr. H. W. Ormerod, Warminster; Messrs. Orridge and Co., Lond.

P.—Mr. J. L. Prichard, Llanfair, Pwllgwyngyll; Messrs. Parke, Davis, and Co., Lond; Mr. Edgar Penman, Lond.; Mr. T. H. Powell, Lond.; Mr. J. E. Pickering, Lond.; Messrs. J. Parker and Co., Lond.; Mr. Y. J. Pentland, Edinburgh; Plumbers' Company, Lond.

R.—Mr. C. Randolph. Milverton; Mr. S. H. Rowley, Swadlincote; Mr. E. J. Reid, Lond.; *Rivista Quindicinale di Psicologia, &c.*, Rome, Editor of; Royal Society, Lond.; Messrs. Reynolds and Branson, Leeds; Royal Hospital for Children and Women, Lond., Secretary of; Dr. D. Ross, Lond.; Royal College of Physicians of Ireland, Registrar of; Messrs. G. M. Restall and Son, Birmingham; Royal York Baths, Lond., Manager of.

S.—Dr. W. J. Smyth, Bournemouth; Messrs. Spiers and Pond, Lond.; Sufferer, Lond.; Dr. H. Scurfield, Sunderland; Dr. R. J. Smith, Cardiff; Mr. E. S. Smith, Liverpool; Sanitary Wood Wool Co., Lond.; Dr. E. J. Smyth, Lond.; J. T. Segrue, Ltd., Lond.; Sanitas Co., Lond.; Messrs. Street and Co., Lond.; Mr. W. P. Stocks, Salford; Smith, Lond.; Dr. R. Sevestre, Leicester; St. Mungo's College, Glasgow, Secretary of; Dr. A. J. Sharp, Whitby; Seamen's Hospital Society, Greenwich, Secretary of; Sunderland Borough Lunatic Asylum, Clerk of; Messrs. Street Bros., Lond.

T.—Mr. J. Thompson, Boston; Dr. J. A. Turner, Hertford; The State Children's Aid Association, Lond., Secretary of; Mr. A. G. Tribe, Treorchy; Sir W. Turner, Torquay; Dr. S. J. Taylor, Norwich.

U.—University of Durham College of Medicine, Secretary of.

V.—Mr. J. W. Vickers, Lond.; Volunteer Medical Association, Hon. Secretary of; Messrs. C. Vaux and Sons, Sunderland.

W.—Mr. S. Wall, Oldham; Dr. P. W. Williams, Clifton; Wills, Ltd., Lond; Mr. H. P. Wilkinson, Powick; Mr. E. Willson, Oxford; Dr. Weber, Rome; Messrs. Wright, Layman, and Umney, Lond.; Messrs. Whitaker and Co., Lond; Mr. T. M. Watt, Lond.; Mr. J. Westmorland, Macclesfield; Worthing Corporation, Town Clerk of, Wolverhampton General Hospital, Secretary of; Mr. F. Wilson, Lond.

Z.—Messrs. A. and M. Zimmerman, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. W. Antony, Dublin; A. R., Lond.; Alpha, Ramsgate; Mr. G. B. Atkinson, Long Clawson; Ætas, Lond.; A. B., Lond.

B.—Mr. G. H. W. Bennett, Sandbach; British Medical Temperance Association, Treasurer of; W. H. Blackburn, Bradford; Messrs. Bowen and McKechnie, Lond; Mrs. Blacker, Southampton; B. W., Lond.; Mr. E. H. Beaman, Misterton; *Birmingham Daily Post*; Beta, Lond.; Mr. C. Birchall, Liverpool; Mr. J. H. Booth, Chesterfield; Mr. H. H. Beale, Reading; Dr. H. C. Bastian, Lond.; Bromide, Lond.

C.—Mr. W. R. Cumming, Mill Hill; Corporal, Lond.; Mr. W. Cox, Winchcombe; C. F., Lond.; Camera, Lond.; Dr. A. Court, Staveley; Mrs. A. M. Campbell, Lond.; Dr. S. Conner, H.M.S. *Albacore*, Queenstown; Messrs. Carless and Mackay, Devizes; Mr. T. Cooke, Lond.; Dr. G. W. Cordwent, Milverton; Mr. A. H. Cheatle, Lond.; City Medicus, Lond.; Colliery, Lond.

D.—Dr. C. V. Dingle, Middlesbrough.

E.—E. S. A., Lond.

F.—Miss M. J. Fergusson, Broughty Ferry; F. S., Lond.; Fromms Extract Co., Lond.; Messrs. Fletcher, Fletcher, and Co., Lond.

G.—Dr. A. Gardner, Kirby Moorside; Guest Hospital, Dudley, Secretary of; G., Faversham; G. G., Leeds.

H.—Dr. D. Henderson, Llandeilo; Mr. J. Hamilton, Swadlincote; Messrs. R. Hogg and Son, Lond.; Miss L. Howse, Lond.; Home, Lond.; Hospital for Diseases of the Throat, Lond., Secretary of; H. F., Lond.; Dr. T. W. Hime, Bradford; Mrs. Hunt, St. Albans.

I.—I. J., Lond.

SYR. HYPOPHOS. CO. FELLOWS.

IMPORTANT.

Experiments have been made by chemists to concentrate still further many of the old formulæ which are prescribed daily by the Profession. This has been found impracticable as applied to the SYRUP OF HYPOPHOSPHITES, as, after many trials, the results obtained by the administration of the condensed preparations in several other forms have fallen far short of those obtained by the Syrup.

"The compound is skilfully prepared. ..... May be given with confidence in cases of nervous debility."—THE LANCET.

"An excellent tonic in the debility of phthisis and strumous conditions generally."
BRITISH MEDICAL JOURNAL.

SYR. HYPOPHOS. FELLOWS. "This excellent compound, as prepared by Mr. Fellows, may be fairly described as the 'ne plus ultra' of tonics, combining as it does all the valuable constituents of Easton's and Parrish's preparations."
BIRMINGHAM MEDICAL REVIEW.

Re PHENACETINE.

IMPORTANT WARNING to MEDICAL MEN.

As discoverers and original makers of this **safe and valuable antipyretic,** we consider it to be our duty to **warn** the Medical Profession that an adulterated substance is now on the market, and is being sold as genuine Phenacetine. (*Vide* current Chemical and Pharmaceutical periodicals.) Our name is so well known in connexion with this product, that, for our reputation's sake, we are compelled to issue this notice.

Medical Men can protect themselves and their patients, and can rely upon obtaining a thoroughly pure product by adding the name BAYER when prescribing Phenacetine.

PHENACETINE-BAYER

is the pure and original product: the name is a guarantee of purity. Phenacetine-Bayer is put up in 4, 5, 8, and 16 grain Tablets, as well as in the Powder and Crystal form.

Samples and Literature can be obtained on application to the Wholesale Depots for all Bayer's Pharmaceutical Specialities—

19, ST. DUNSTAN'S HILL, LONDON, E.C.
Also at MANCHESTER, GLASGOW, and BRADFORD.

TRADE MARK 'TABLOID' BRAND

BLAUD PILL

IT rarely happens that the clinical investigator is able to state the physiological results of the action of drugs with mathematical precision. When preparations of iron are administered an exception to the general rule is encountered. By estimating the increase of haemoglobin in the blood of patients the therapeutic action of iron can be ascertained and the relative values of various methods of administering it accurately compared.

A prolonged and comprehensive investigation was recently undertaken at the Hospital for Diseases of the Heart, Soho Square, and it was then definitely ascertained that 'Tabloid' Blaud Pill caused an increase of haemoglobin of 1.2 per cent. per diem, whereas in the case of all the other preparations it never exceeded 0.5 per cent.

Full particulars of these investigations will be forwarded to physicians who desire them.

'TABLOID' BLAUD PILL, 4 gr. (plain or sugar-coated).

'TABLOID' BLAUD PILL, 4 gr. with Arsenious Acid, 1/64 gr.

'TABLOID' BLAUD PILL, 4 gr. with Aloin, 1/20 gr.

H. K. LEWIS'S STANDARD PUBLICATIONS.

Just published, THIRTEENTH Edition, thoroughly revised, 8vo, 16s.

A HANDBOOK OF THERAPEUTICS.

By SYDNEY RINGER, M.D., F.R.S.,

Holme Professor of Clinical Medicine in University College; Physician to University College Hospital; and

HARRINGTON SAINSBURY, M.D., F.R.C.P.,

Physician to the Royal Free Hospital and the City of London Hospital for Diseases of the Chest, Victoria Park.

"We welcome a new edition of this familiar work, which still remains one of the most useful alike to student and practitioner. The article on Serum Therapeutics is excellent. The admirable introduction on symptoms as a guide to prognosis and treatment ought to be studied by every practitioner."—LIVERPOOL MED.-CHIR. JOURNAL.

"One of the most essentially practical and useful therapeutic works in existence."—NEW YORK MEDICAL JOURNAL.

Just published, with 13 Plates and other Illustrations, crown 8vo, 10s. 6d.

DISEASES OF THE NERVOUS SYSTEM.

A HANDBOOK FOR STUDENTS AND PRACTITIONERS.

By CHARLES E. BEEVOR, M.D. Lond., F.R.C.P.,

Physician to the National Hospital for the Paralysed and Epileptic, the Great Northern Central Hospital, and the National Orthopædic Hospital.

[*Lewis's Practical Series.*

"The author is to be congratulated on having produced a treatise on nervous diseases which is likely to be as interesting to the general reader of medicine as to the specialist. The remarks on treatment are excellent and practical throughout. We feel sure that Dr. Beevor's book will be of the greatest value both to the student and practitioner."—BRITISH MEDICAL JOURNAL.

Just published, FIFTH Edition, thoroughly revised, with 4 Plates and 174 Illustrations, crown 8vo, 10s. 6d.

A PRACTICAL TEXT-BOOK OF THE DISEASES OF WOMEN.

By ARTHUR H. N. LEWERS, M.D. Lond.,

Obstetric Physician to the London Hospital, and Joint Teacher of Practical Midwifery at the London Hospital Medical School; Examiner in Midwifery and Diseases of Women at the Conjoint Board of the Royal College of Physicians, London, and Royal College of Surgeons, England, &c.

[*Lewis's Practical Series.*

"This work can be recommended to practitioners and students as giving a concise view of the present state of gynæcological knowledge and practice."—THE LANCET.

"One of the safest guides upon diseases of women both for the practitioner and student."—BRITISH MEDICAL JOURNAL.

"The work has the advantage of being thoroughly practical. To the student we heartily recommend this little book as handy in size and sound in material."—BRITISH GYNÆCOLOGICAL JOURNAL.

"We congratulate Dr. Lewers upon having produced one of the most readable and valuable of a valuable series. No better book could be given a student or practitioner anxious to brush up his gynæcology."—LIVERPOOL MED.-CHIR. JOURNAL.

"In it the author has fully succeeded in showing what a practical text-book for students should be. From preface to finish the style and matter are eminently practical and clinical."—EDINBURGH MEDICAL JOURNAL.

FIFTH Edition, with numerous Illustrations, crown 8vo, 10s. 6d.

HYGIENE AND PUBLIC HEALTH.

By LOUIS C. PARKES, M.D., D.P.H. Lond. Univ.,

Fellow of the Sanitary Institute; Lecturer on Public Health at St. George's Hospital Medical School; Medical Officer of Health for Chelsea.

[*Lewis's Practical Series.*

"Fully maintains the standard of excellence to which its popularity is due."—BRITISH MEDICAL JOURNAL.

"The qualities which have made the manual so deservedly popular in the past are fully maintained."—PRACTITIONER.

"The book is an excellent one in all respects, and is worthy of the high reputation of its author. ..... May be thoroughly relied upon."—SANITARY RECORD.

"A very safe guide for those who desire to possess knowledge on the varied subjects of hygiene and public health."—GLASGOW MEDICAL JOURNAL.

NINTH Edition, in One Volume of over 1100 pages, with Illustrations, large 8vo, 21s.

THE THEORY AND PRACTICE OF MEDICINE.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P.,

Professor of the Principles and Practice of Medicine in University College; Physician to University College Hospital, &c.

"Dr. Roberts's 'Theory and Practice of Medicine' is so well known, and has been for so long deservedly appreciated both by students and practitioners of medicine, that no words of ours are necessary to increase its popularity. There is no more suitable book on general medicine than Dr. Roberts's. The present edition has been brought fully up to date."—THE LANCET.

SIXTH Edition, with Illustrations, post 8vo, 12s. 6d.

Handbook of Diseases of the Eye and their Treatment. By Henry R. Swanzy, A.M., M.B., F.R.C.S.I., Examiner in Ophthalmology to the University of Dublin; Surgeon to the National Eye and Ear Infirmary and Ophthalmic Surgeon to Adelaide Hospital, Dublin.

"We are glad to welcome another edition of this excellent manual."—THE LANCET.

"Will especially recommend itself to the student and practitioner anxious to know all that should be known without unnecessary detail."—BRITISH MEDICAL JOURNAL.

Illustrated with Plates, Diagrams, and Charts, demy 8vo, 15s.

A Manual of Infectious Diseases. By E. W. Goodall, M.D. Lond., Medical Superintendent of the Eastern Hospital of the Metropolitan Asylums Board; formerly Medical Registrar to Guy's Hospital; and J. W. WASHBOURN, M.D. Lond., F.R.C.P., Physician to the London Fever Hospital; Assistant Physician to Guy's Hospital, and Lecturer in the Medical School.

"The authors have produced an excellent and well-balanced hand-book."—THE LANCET.

"The authors have produced a work of great value to general practitioners and students of medicine."—GLASGOW MEDICAL JOURNAL.

"A beneficial text-book on a most important subject, well written and well illustrated."—DUBLIN MEDICAL JOURNAL.

"An excellent addition to the text-books."—EDINBURGH MEDICAL JOURNAL.

SECOND EDITION, with numerous Illustrations, large 8vo, 24s.

Diseases of the Skin; their Description, Pathology, Diagnosis, and Treatment. By H. RADCLIFFE CROCKER, M.D. Lond., F.R.C.P., Physician for Diseases of the Skin in University College Hospital, and late Physician to the East London Hospital for Children.

"We have much pleasure in expressing the opinion that the work is a highly creditable testimony to Dr. Crocker's zeal, clinical acumen, and accuracy of observation, and that it will take a good place amongst the excellent manuals that have lately appeared in this country."—BRITISH MEDICAL JOURNAL.

LONDON: H. K. LEWIS, 136, GOWER STREET, W.C.

A Clinical Lecture

ON

TWO CASES OF INJURY TO THE HEAD.

Delivered at St. Mary's Hospital on March 4th, 1898,

BY HERBERT W. PAGE, M.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO THE HOSPITAL.

GENTLEMEN,—From time to time I have taken cases of head injury as the subject of clinical lectures and more than one of them has been published, but it is doubtful whether we have had before two cases of as much interest and instruction as those which I propose to-day to put side by side as the theme of clinical remarks. The first was that of a man, aged forty-nine years, for an account of whose history I shall draw from the admirable notes taken by Mr. Wells. He was brought to the hospital at 1.15 P.M. on Dec. 21st, 1897. He was a guard on the Metropolitan Railway and in the discharge of his duties, while in the act of waiting on the platform, in a manner which one sees every day, at Royal Oak Station, for the rear van of the moving train to come up to him, he was knocked down by an open carriage door. He was struck on the front of the forehead between the eyes and then was thrown violently on the back of his head. He was dazed but not unconscious and was brought at once to St. Mary's Hospital, arriving here within a short time of the accident. He was then extremely collapsed but was perfectly conscious. He answered questions and gave both his name and address. Blood and cerebro-spinal fluid were flowing from the left ear; his respirations were 20 and his pulse was 90. No fracture could be detected by external examination, but there was a bruise in the front of the forehead and some slight swelling over the left temporal region. The pupils were equal and reacted, though sluggishly, to light. There were no one-sided symptoms of any kind whatever, the bleeding from the ear alone excepted.

Let us here pause for a moment in the history. Up to this point of it the conclusion seemed warranted that the man had sustained a pretty severe concussion of the brain and in all probability a fracture of the base of his skull. The serious nature of his injury admitted of no doubt and in a case of the kind it would be no great surprise if in the course of the next few hours some more definite evidence than collapse and bleeding from the ear should arise to increase the anxiety about him. The scene changed with remarkable suddenness, and returning to the notes we learn that soon after being put to bed he began to lose consciousness, so that when I reached the hospital at 2 P.M., three-quarters of an hour after his arrival, the coma was fairly profound. In this interval there had been some clonic movements of the left arm, but these had quickly given place to spastic rigidity, which quickly involved all the limbs equally. When I first saw him cutaneous stimuli, such as pinching and pulling his hair, made little impression, and I could hardly believe that so short a time ago the man had actually given his name and address. The coma at once suggested that the brain was being subjected to compression, and as I stood beside him for a minute or two it was obvious to all that the unconsciousness was deepening, that both pulse and respiration were failing, and that artificial respiration might become necessary. Another indication of supreme importance was also present, for the pupils, which before had told us nothing, now told a great deal. No longer equal and mobile, they were now fixed and unequal, the left being much larger than the right. Clearly there was no time to lose if we were to give relief. Within a quarter of an hour of my arrival the man was in the theatre and we had begun to shave his head preparatory to opening his skull. This we proceeded to do in the usual way over the left middle meningeal, it being a warrantable assumption that inasmuch as there was bleeding from the left ear and the left pupil was dilated, suggestive of pressure on the left third nerve at the base of the skull, there might be bleeding from a branch of this vessel to which brain compression and the resulting coma were due. Opening having been made by the trephine it was at once evident that there was no hæmorrhage between the dura mater and the bone and that the suspected cause of compression must be sought for elsewhere. Those of you who saw the man on the table will remember that the dura at once bulged prominently into the trephine hole and that it had the blue appearance which is so striking when there is blood beneath it. Furthermore, no brain pulsation could be felt. I therefore proceeded to open the dura freely and this at once gave exit to a considerable amount of blood. Feeling confident, however, that the extravasated blood lay chiefly at the base of the skull a small tube attached to the irrigator was passed down to this part and a very considerable quantity of blood, both fluid and clotted, was thus washed out. The effect was remarkable, for not only did the respiration and pulse materially improve but, what is of greater interest, the left pupil now became of the size of the right and was no longer dilated. This, unhappily, was the full measure of the improvement, and inasmuch as the bleeding came from some inaccessible source there was no alternative but to sew up the wounds and to send the man back to bed. I had no hope that his life could be saved. As a matter of fact he never regained consciousness and died at 8.30 P.M., the respiration having at times been extremely laboured and somewhat like Cheyne-Stokes in character, the pulse having been as high as 169, the temperature having steadily risen to 107° F. immediately before death, and more bleeding having obviously occurred. The necropsy was made by Mr. Low and I was myself present at it. I wish you had been present also, for you would have had the opportunity of seeing in an unusual degree one of the varieties of intracranial hæmorrhage as the result of injury. The so-called sub-arachnoid space over both hemispheres was practically filled with blood, fluid and clotted, but the greatest quantity of blood was at the base, and it had evidently accumulated again in much the same position and amount as we had seen on the operation table. Doubtless it had come from more vessels than one. Extensive laceration of the left orbital lobe and of the anterior extremities of both temporal lobes was found, but the internal parts of the brain were unaffected. There was most extensive basal fracture, for not only were several of the sutures sprung, but lines of fracture ran longitudinally from the sutures and also transversely through the basilar process. These fractures must, I think, have been caused by the fall on the back of the head and not by the blow on the brow, for the lambdoid suture was sprung and gaped almost throughout its entire length. With such lesions it is no wonder that the patient died, but it is at any rate remarkable that he should for a time have been conscious and been able to give his name and address on arrival at the hospital.

I ask you to bear this fact about the case in mind, for the second case which I will briefly relate to you presented in less degree the same features. For the notes I am indebted to Mr. Hunt. From these we learn that a man, aged fifty years, was admitted into St. Mary's Hospital on Jan. 14th, 1898. While walking on the Metropolitan Railway he was caught in the back by the buffer of an engine and knocked down so that his head came violently in contact with the edge of some iron girders lying on the ground. On admission he was half unconscious and brain matter was protruding from a severe lacerated wound over the left temple. The finger at once detected that there was considerable comminution and depression of bone and we had the patient moved straightway to the theatre. He was not so unconscious that we could do without the aid of an anæsthetic, and the parts having been exposed fragments amounting in all to something larger than a five-shilling piece were removed from the temporal and parietal bones. The membranes were extensively lacerated and the finger passed into a large area of broken-up cerebral matter. This being so it will be no surprise to hear that the man was absolutely hemiplegic on the right side. Moreover, his breathing was entirely diaphragmatic. The pupils were unequal, the left being the larger, and both reacted to light. The patient never regained consciousness and before his death on the morning of the 17th the temperature had risen to 104° F. Mr. Low made the post-mortem examination, but was permitted to examine the head only, an unfortunate restriction, because the mode of accident and the after-symptoms rather suggested that the man might have received some injury to the spine as well as to the head. The fracture involved the

squamous portion of the left temporal and adjoining parietal bones and the damaged parts of the brain included the lower part of the left Rolandic area and the upper part of the temporo-sphenoidal lobe. There was extensive sub-arachnoid hæmorrhage over both hemispheres and the upper surface of the cerebellum. Save the lateral ventricles, both of which contained some blood-stained fluid, the internal parts of the brain appeared to be normal.

I have purposely put these two cases in apposition, because although both of them were inevitably fatal they serve to throw into the prominence of contrast the sort of evidence for which the surgeon seeks in all severe head injuries that he may determine whether or not he is likely to be able to save life by resort to surgical measures. As far as injury to bone is concerned it goes without saying, in these days of asepsis, that there ought never to be hesitation or delay in removing useless fragments of displaced bone or in restoring bone or portions of bone to their normal position and it was on this principle that we acted in the second case, where a large piece of the side of the skull had been driven in. You have seen many cases thus successfully treated, but unhappily in this instance the extent and character of the injury sustained by the brain itself rendered operative proceedings futile. An absolute hemiplegia following a compound depressed fracture and not relieved by the elevation of bone told its own tale. In the first case, however, a totally different condition of things presented. No *direct* evidence of fracture was to be obtained—in basal fractures there rarely is—and certainly as far as the skull was concerned there was no reason for resort to operation. Nevertheless, I felt that in the first case much more than in the second the need for operation was urgent and I was much more anxious to have the patient quickly on the table in order to open his head. For we were in the presence of this most suspicious indication of intracranial pressure, the result of injury, that the man had become more and more unconscious each minute that he was in bed, having originally as you remember been distinctly conscious and able to give his address and name. To the very partial loss of consciousness which first characterised his state when the collapse was extreme there was clearly being something added to produce unconsciousness in an increasing degree the further he was removed in time from the collapse in which he first came to the hospital. The strong presumption therefore was that bleeding was going on within the cranium and that the brain was being gradually compressed and rendered anæmic and functionless by the squeezing to which it was being subjected. Here, indeed, was incontrovertible evidence of the need for resort to surgical measures in the hope of averting the peril of death. Was the trephine hole, however, to be made at any haphazard spot? Clearly not; and the question had to be asked, What in the circumstances was the probable source of bleeding? The answer to this question admitted of little doubt. From the anterior or other branch of one of the middle meningeal arteries, the proximity of that vessel to the bone making it liable to be torn across in cases of fracture and frequently to be the source of hæmorrhage between the dura mater and the bone. But you will ask why we chose the left side. For this weighty reason, that there had been bleeding from the left ear and that in the progress of the coma the left pupil had become dilated and larger than the right. It is an established fact that in middle meningeal hæmorrhage this symptom is of not uncommon occurrence, because the clot of blood in increasing tends to make its way towards the base of the skull and pressing forwards on the sphenoidal fissure there directly interferes with the function of the third nerve.

Many years ago in a clinical lecture[1] Mr. Hutchinson directed attention to this phenomenon as regards the pupil and the cases he records are worth mentioning. In one case, that of a boy admitted to hospital with slight concussion of the brain and indications of fracture in the anterior part of the base, it was noticed on the second day after admission, when consciousness had been to a large extent regained, that the right pupil, which had previously been of the same size as the left, had become dilated and fixed. A few hours afterwards the house surgeon found the boy insensible, with difficult and irregular breathing, and within a few minutes the patient died. He had been conscious up to within half an hour of his death and beyond the symptoms which usually attend severe concussion there was none excepting the dilatation of the right pupil. After death a fracture was found crossing the line of the meningeal artery and there was a large clot of blood between the dura mater and the bone extending downwards into the sphenoidal fissure and compressing the third nerve. In another case with the like symptoms precisely the same condition of things was found and many cases have been recorded since by other surgeons. I show you a drawing of the sort of fracture which may be associated with rupture of the middle meningeal artery. The line of fracture is in this case vertical, running to the base and passing through the anterior inferior angle of the parietal bone, but the same thing may happen when the fracture is horizontal in direction. Do not go away with the idea that pressure of blood is the only cause of a dilated pupil, but do not in any case fail to attribute to it such value as accompanying indications may seem to warrant. For these you will, of course, always look; for evidence of the direction of the fracture if any there be, for indications of paralysis, at the character of the coma and the period of its onset, at the state of both respiration and circulation and any marked change in either,—these in combination and each one separately may help in the diagnosis or in the attempt to arrive at one. Certain diagnosis is, however, often impossible, approximate diagnosis is perhaps the best to be attained to, erroneous diagnosis is to be excused, and increasing experience will only tend to teach you that in head injuries the symptoms will too frequently belie the classical indications of this or that lesion. Every case, however simple, presents its own problems to be solved.

Let us return, however, from this digression to our own case and ask if we were right in our conclusions and in what we did. We were both right and wrong—right in the conclusion that the brain was being subjected to pressure, right also in using the trephine, but wrong in our conjecture as to the source of the blood. Here conjecture alone is possible, for it is obvious that in these cases until the opening has been made there is no means of telling which vessel may be bleeding within the skull and we must be prepared to find a condition of things for which no relief can be given. In a case which I have published we found ourselves in the same dilemma. Intracranial hæmorrhage had been correctly diagnosed from symptoms of intense urgency, but the source of the hæmorrhage was a rent in one lateral sinus and the bleeding could not be stayed. It is, however, a great thing in any case to be able to speak with comparative certainty as to the existence of intracranial bleeding, for relief may perchance be given if resorted to without delay. So great, however, may be the urgency that artificial respiration alone will keep the patient alive until his head has been opened. I have already touched on the several indications which really guide us, but they are very likely to be missed unless the patient be carefully watched minute by minute. My last house surgeon, Mr. Hanson, deserves, therefore, every credit for his careful observation of this man's condition and I would commend to you the exercise of the same care in all cases of head injury.

In this connexion may anything be said of our second case and the symptoms which were there present? Increasing unconsciousness and one-sided phenomena are the very things which have been named as likely to be of value in determining whether the brain is being compressed. We knew, however, by the simple observation that there was a large open fracture and the skull was no longer a closed cavity that the symptoms could hardly be due to intracranial pressure. Under these conditions intracranial pressure was well-nigh impossible, depression of bone is *per se* an insufficient cause of it, and had blood been extravasated it must either itself have escaped from the wound or caused cerebral matter to protrude. Things might perhaps be different were blood extravasated in large quantity beneath the tentorium cerebelli. From this point of view, therefore, the contrast of the two cases is worthy of our notice. Had they aught in common? In both of them there was extensive injury to the brain and in both also there was great rise of temperature, an indication perhaps of the severity of the brain lesions and of the degree in which the cerebral control had been withdrawn from the processes of organic life. This also they had in common, that their end was the same. I wish it could have been otherwise, but it is impossible to forget or deny that many cases of head injury are inevitably fatal from the character and severity of the injuries to the brain itself. It is, moreover, because of the multitudinous effects of the

[1] London Hospital Reports, vol. iv., 1867.

injuries to the brain that precise symptoms of this or that lesion are so often masked and obscure and that certain diagnosis is so difficult. Shall the surgeon therefore withhold his aid? Rather let him look the more carefully for any indications to tell him whether relief may perchance be given by exploratory operation. He may fail, but to abandon the patient to his fate may not be the best that he can do. A life may now and then be saved where the actual condition could only thus have been determined and where relief could have been brought in no other way.

ABSTRACT OF

The Hunterian Lectures

ON

THE SURGERY OF THE KIDNEY.

Delivered before the Royal College of Surgeons of England on March 21st, 23rd, and 25th, 1898.

BY HENRY MORRIS, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE III.[1]

Delivered on March 25th.

FISTULA CAUSED BY RENAL CALCULUS; OBSTRUCTIVE ANURIA DUE TO RENAL CALCULUS; THE TECHNIQUE OF THE EXPLORATION OF THE KIDNEY AND URETER FOR CALCULUS.

MR. PRESIDENT AND GENTLEMEN,—In the second lecture I endeavoured to show (1) that the errors and uncertainties in the diagnosis of renal calculus had in many instances been of distinct advantage because they had led to the exploration of the kidney and this in turn to the discovery and cure of various morbid conditions other than those due to stone; (2) that unsuspected, quiescent, and migratory renal calculi cause very destructive and even fatal consequences and that we ought to revise our practice with regard to the early treatment of renal calculus; and (3) that the low mortality of nephrolithotomy (i.e., the operation for renal calculus in its early stages), and the high mortality of nephrotomy, and the still higher mortality of nephrectomy (i.e., of the operations performed for the advanced disorders due to renal calculus) show the advisability of operating at as early a stage as possible. In further support of this conclusion I may point to the exploratory operations and the operations for moveable kidneys. There are 42 of the former and 57 of the latter without a death due in any way to the operation.

At the Middlesex Hospital, where renal operations are freely undertaken by the members of the surgical staff, a good many persons nevertheless die from the effects of renal calculus who are too ill to be operated upon when admitted. During the years 1885 to 1895 inclusive calculi were found in the kidneys in 45 out of 3331 post-mortem examinations, and hydronephrosis due to calculus impacted in the ureter was found in 4 others. That is, in 1½ per cent. of persons dying from all causes calculi were found in one or both kidneys or ureters. Many of these 45 bodies found their way to the post-mortem room entirely because of calculous disease, and in the rest renal calculi contributed more or less to the fatal result. Amongst the 45 cases there were 10 instances of suppuration in one or both kidneys; 11 cases of perinephric abscess; 4 cases in which calculi were present in both kidneys; and 4 others in which only one kidney could be said to exist, the other having undergone complete atrophy due to obliterated ureter in three of them and cystic degeneration from obstruction in the fourth. Besides these 45 cases there were 63 instances of suppurative nephritis, in most of which both kidneys were affected, and in many of them renal calculus had played a conspicuous part.

FISTULÆ.

In considering the harmful effects of renal calculi it is impossible to leave out of account renal and ureteral fistulæ. It is after nephrectomy for calculous pyonephrosis especially that a fistula due to operation is most likely to occur. It is exceptional for a permanent or long-standing fistula to result from nephrolithotomy, or an operation for movable kidney, or a simple exploration. Fistula is also exceptionally rare after nephrectomy except when perinephritis or perinephric abscess has previously existed. In cases of nephrectomy for calculous disease perinephritis, however, has usually preceded the operation, but in spite of this a fistula followed in only one out of twelve of my surviving nephrectomies for stone, and in that case the fistula was superficial and probably healed shortly after the patient left the hospital, though I have no certain knowledge that it did so. Out of my 33 nephro-lithotomies which survived a superficial sinus occurred in two and a urinary sinus in two. In the two latter very large incisions involving the pelvis of the kidney had to be made for the extraction of stones of great size. After nephrotomy for advanced calculous conditions—e.g., calculous pyonephrosis—fistulæ, either temporary or permanent, occurred in 37·5 per cent. of the cases operated upon. Though in many of these the fistulæ subsequently healed, still the fact that even a temporary fistula followed in so large a proportion of cases affords a further argument in favour of early operation for stone in the kidney. But the fistulæ which occur independently of any operation, which are due, in other words, to long-retained renal calculi, should appeal even more strongly to surgeons as an argument against delaying operative treatment for stone. The persistency of these fistulæ, the recurrence of deep suppuration if the external orifice of the fistula is allowed to close, together with the abiding troubles caused by the continued presence of the stone in the kidney or ureter, will sooner or later induce the patient to demand surgical assistance. Then the patient has to undergo risks and the surgeon to face difficulties which only occur when the perinephric structures are matted and hardened by long-standing inflammation or suppuration and have become so densely adherent to the kidney capsule that it is often no easy matter to find the kidney.

Another and very important fact is that these condensed contracted tissues fill the hilum and surround the whole of the kidney with a fibro-lipomatous mass which shortens and stiffens the pedicle and compresses and destroys the elasticity of the renal vessels and of the ureter. The result of this is that the kidney gets tucked close up against the spinal column and as firmly set in its surroundings as if it were embedded in plaster-of-Paris. If nephrotomy is done under these conditions the renal artery cannot be controlled when the renal parenchyma is incised and the kidney cavity is explored and thus bleeding is apt to be very free. If nephrectomy is performed the risks and difficulties in dealing with the pedicle are enormously increased. When a fistula is in course of formation the perinephric abscess should be opened as soon as possible lest the matter should burrow and discharge in some dangerous direction. It is true the abscess will often make for the loin or groin and open spontaneously on the surface if it be not incised, but it should not be suffered to do so. It is, however, as a rule unsafe to search for and explore the kidney when the tissues surrounding it are in an acutely suppurating condition. The safer course is to defer the exploration of the kidney till after the abscess is healed. This necessitates a lengthy convalescence followed by a fistula and a second operation before the cause of the abscess can be removed. After this second operation, whether it be nephrotomy or nephrectomy, it is not unfrequent for the healing of the wound to be delayed by profuse and prolonged suppuration.

The same drawbacks attend operations for calculous affections of long standing if perinephritis without abscess or fistula has existed. If perinephritis has commenced before nephrotomy is performed neither the extraction of a calculus nor the evacuation of pus from the renal cavity may prevent the spreading of the inflammatory process in the surrounding cellular tissue and the formation of a fistula at a long distance from the kidney.

The closure of the fistula by surgical treatment is tedious and sometimes impossible; and in some cases, after having been successfully treated, and remaining closed for many months or a year or two, it will reopen. Those which do not communicate with the kidney or ureter should be treated on the ordinary principles applicable to all fistulæ; those which do so communicate must be dealt with differently in different cases. If there is a calculus in the kidney it must be removed; if the kidney

[1] Lectures I. and II. were published in THE LANCET of April 16th and 23rd, 1898, respectively.

is quite disorganised nephrectomy is requisite; if the kidney is not disorganised the fistulous track should be cut out and the cut surfaces united by sutures. When no stone is found in the kidney the ureter will probably be the seat of some kind of obstruction. There may be an impacted calculus, a stricture following inflammation or ulceration caused by a calculus which has escaped, or a stricture as the result of contraction after periureteritis, or the duct may be distended in one part and contracted in another by suppurative ureteritis. In most cases a renal or ureteral fistula of calculous origin will, I believe, close permanently after nephrectomy even if a stone be left impacted in the ureter or the ureter be in a state of suppuration at the time of the operation. But should it not do so it may be necessary, as in the case of fistula kept up by tuberculous ureteritis, to perform partial or complete ureterectomy. A urinary fistula due to obstruction in the ureter may in time cease to discharge urine owing to complete atrophy of the kidney. The length of time required for this to be accomplished depends on the degree of obstruction which the fistula, on the one hand, and the ureteral block on the other hand offer to the escape of urine. The more complete the obstruction the more rapid the atrophy and *vice versâ*. In a case of my own the process took seven years.[2] Even after a fistula ceases to be urinous it may persist as a suppurating sinus.

Two objections to early operations for renal calculus are: (1) that calculi will be missed if sought for very early because of their small size; and (2) that very small calculi, if they once enter the ureter, pass through the urinary passages without risk to life. Both these objections are unsound and lead to dangerous delay. In the lists of my operations for calculus it will be found that stones of all sizes, from two grains to ten ounces, have been removed by nephro-lithotomy or nephrotomy; and I do not think one, however small, will be missed because of its small size with the present method of exploring the kidney and ureter. The second objection is more invalid than the first, for there is ample proof that a very minute calculus may provoke the complete destruction of the kidney or become the immediate cause of death from suppression of urine. In some of my cases the most continuous and profuse hæmaturia has been caused by small stones. But—worse than hæmaturia or the destruction of a kidney—calculi weighing less than two grains have caused death. Sir William Roberts, in his admirable chapter on "Obstructive Suppression of Urine," records a case where three little oxalate of lime calculi about the size of hemp seeds, and weighing altogether one and a half grains, were found in the lower part of the ureter, where it passed through the coats of the bladder; this was the cause of the obstruction which resulted in the death of the patient from anuria.

CALCULOUS ANURIA.

Calculous anuria is the gravest and most fatal of the many serious complications of renal lithiasis. Special attention was given to it in 1872 by Sir William Roberts in the second edition of his classical work on "Urinary and Renal Diseases" (p. 23, *et seq.*); and in 1881 an exhaustive thesis on anuria by Pierre Merklen was published in Paris; but neither in this nor in Sir William Roberts's book is the subject of the surgical treatment of calculous anuria considered. In his 1885 edition Sir William Roberts, it is true, says in a footnote: "Lately it has been recommended to open the ureter or pelvis of the kidney above the obstruction and so establish a permanent urinary fistula." But though anti-spasmodics and a variety of mechanical means are recommended and diuretics are rightly condemned, still surgical aid was not seriously discussed by either Sir William Roberts or Merklen. Even at the present time the principle of the operative treatment of calculous suppression of urine is either imperfectly known or improperly appreciated by the profession in this country, because operations are certainly neither sufficiently early nor sufficiently often performed. Worst still, patients are sometimes told that no surgeon in his senses would dream of an operation in their condition. Since 1885 excellent theses on this subject have appeared in France by Legueu, Donnadieu, Glantenay, and Vailhen; and in England, though nothing bearing generally on the surgical treatment of calculous anuria has been published, some brilliantly successful operations by the lumbar route have been reported, notably by Clement Lucas, Ralfe and Godlee, and Kirkham, who were amongst the first English surgeons to operate in these cases.

Etiology.—Calculous anuria occurs when the ureter or renal pelvis of one kidney is occluded by a calculus, the other kidney being absent, atrophied, or diseased. It often affects persons in robust health and may be sudden and complete in its onset. It is then due to the cessation of function of a kidney which has undergone compensatory hypertrophy and which up to the moment of obstruction had been secreting the whole or the chief part of the urine. Occlusion of one ureter never gives rise to fatal anuria if the opposite kidney and ureter are normal.

Anuria may occur at any age and in either sex; it is more frequent in males of thirty-five years and upwards and more especially in elderly men. Instances of children and even infants at the breast dying from convulsions from calculous suppression have been recorded (Rayer). Much importance ought to be attached to the antecedent history of patients who become the subjects of suppression of urine from ureteral obstruction. Commonly they have had several previous attacks of renal colic or of lumbar pains followed by the discharge of gravel or small stones months or even years before the attack in which the anuria begins. But cases have occurred of sudden suppression of urine from obstruction by a calculus without a previous attack of any kind. In such cases both kidneys have been simultaneously obstructed or one kidney has been destroyed by disease of another kind or has been congenitally absent or abnormal. Calculous anuria is often determined or immediately induced by fatigue, a drive or some other shaking movement, such as jumping from an omnibus, violent coughing, rapidly running from the garden to the house on hearing a loud peal of thunder, are some of the causes, in my own cases, which started the descent of the calculi from the kidney into the ureter.

Symptoms.—The symptoms of calculous anuria are not simply those of uræmia. Though in rare instances the onset is insidious pain is almost invariably experienced in the region of the kidney involved last at the outset of the suppression. The pain so started may continue throughout the anuria, but more commonly it is temporary, lasting only a day or two or less, and then subsiding. Less frequently the first symptom is a dull and continuous aching in the lumbar region with or without pains radiating along the course of the ureter. In very exceptional cases the anuria has come on without pain on either side and without the history of previous attacks of renal colic, or the patient has quite forgotten on which side the previous attacks of colic were. These, fortunately rare, are the cases in which the surgeon has no guide as to which kidney to operate upon. With the pain there may be troubles of micturition, such as continual desire to pass urine though not a drop of urine may be in the bladder, or the urine is passed with difficulty and sometimes only in drops or teaspoonfuls; or, on the contrary, there may be polyuria, the urine being pale and of low density and showing evidence of imperfect renal function. In other cases the anuria is intermittent, ceasing, after some hours or a few days, to reappear and become definitely established.

Calculous anuria may be complete or incomplete. In the complete suppression the bladder is quite empty or if not contains but a few teaspoonfuls of bloody urine. In the incomplete form the anuria is intermittent but progressive and interrupted by discharges of urine, insufficient to satisfy the requirements of the system but sufficient to retard the fatal termination of the disease. When the working kidney is hydronephrotic the uræmic condition may be deferred for a longer time than otherwise, even if there are no polyuric intermissions. Calculous anuria once established may last many days without causing any symptoms of uræmia. This is perhaps its most striking feature, which it shares with other forms of obstructive anuria, and with anuria from ligation of the ureters, as distinct from the non-obstructive forms. Even when the suppression is complete seven, eight, or ten days may elapse before the symptoms of uræmia appear and sometimes death occurs without any of the characteristic symptoms of uræmic poisoning arising at all. When the uræmic phenomena supervene after a longer or shorter time death follows rapidly or at any rate within a day or two. In the period of tolerance the patient, though he may not pass a single drop of urine for several days, may yet walk about, eat, and do mental work in all the appearance of good health. This fact must never be forgotten if a serious mistake in diagnosis and prognosis is to be avoided.

[2] See Injuries to the Ureter, Edinburgh Medical Journal, January, 1898

It is, however, all the more likely to escape notice because it is so opposed to the course of suppression due to non-obstructive causes. In certain cases polyuria occurs and retards the appearance of uræmic phenomena as well as the fatal termination, which however at length arrives. In Paget's case polyuria occurred on the thirteenth day and death was deferred till the twenty-second day. In Weber's case a succession of remissions of polyuria took place and the fatal result was not reached till the thirtieth day from the onset of the anuria.

Symptoms when hydronephrosis is associated with anuria.—When the working kidney is hydronephrotic patients with calculous anuria may escape uræmic accidents for a much longer time than others without having polyuric remissions. Thus in a fatal case of a man, aged sixty-four years, recorded by Rayer,[3] with an enormous hydronephrosis, the anuria lasted twenty-five days, with only a slight remission on the tenth day. James Russell published a case of anuria lasting twenty days, which terminated by the discharge of ten litres of urine in twenty-four hours; but a year later the patient died and at the post-mortem examination there was discovered double hydronephrosis with calculi in the pelvis of each kidney. Sir William Roberts cites a case of calculous anuria of ten days' duration, with an increasing tumour in the left iliac fossa; recovery followed a veritable urinary crisis coincident with the disappearance of the tumour.

Prognosis.—The usual termination of calculous anuria when left to itself is death about the tenth or eleventh day. If, however, the suppression is interrupted by intermittent polyuria, whether hydronephrosis exists or not, life may be prolonged by many days. Spontaneous cure sometimes occurs. Legueu states that out of 56 cases of calculous anuria, which neither followed nor were treated by operations, recovery took place in 16—i.e., in 28·5 per cent. In 1 the secretion recommenced on the third day; in 10 between the fifth and tenth days; and in the rest on the thirteenth, fourteenth, fifteenth, twentieth, and in two instances on even a still later day. Of the 40 deaths 23 occurred between the fifth and fifteenth days, one on the fourth day, and the rest on and after the sixteenth day. Of the 48 cases not operated upon 38 died and 10 recovered; of the 49 cases operated upon 24 died and 25 recovered. Thus there is a percentage of recoveries in cases operated upon of 51 as against 20·8 in cases not operated upon.

The pathological anatomy of calculous anuria may be summed up in the statement that the ureter or renal pelvis of one side has become recently occluded, whilst the kidney of the other side is either congenitally absent or functionally suppressed, or structurally destroyed by calculus or some other form of renal disease. Rarely does simultaneous obstruction of both ureters by calculi occur, although this has been known to happen.

Diagnosis.—The occurrence of former attacks of renal colic in a gouty person, followed by the sudden onset of pain on one side, and this accompanied or immediately followed by anuria, points at once to obstruction of a calculous nature. The diagnosis will be further strengthened if a swelling or distinct tenderness on pressure is present in the renal region or in the course of the ureter of the side recently become the seat of pain. But in some cases there is not a distinct history of previous attacks of renal colic and yet one kidney may have become silently but entirely obstructed or destroyed by calculi, as shown in Lecture II. In other cases there have been previous attacks of renal colic or pain, but the patient has forgotten on which side the pain was felt. If under these circumstances anuria sets in it may be difficult or impossible to diagnose on which side the recent obstruction exists. The surgeon thus in doubt must seek information by the examination of the patient in the following manner:—1. The course of the ureter should be palpated, if possible, through the abdominal parietes. This is often an impossibility owing to the stoutness of the patient. The ureter in which a calculus is impacted is likely to be inflamed and painful as well as tender; even when a calculus has passed along the ureter it is likely to be followed by pain, lasting several days after its escape. 2. Rectal and vaginal examination should be made. In the male digital examination per rectum has led to the discovery of a calculus impacted in the lower part of the ureter, as in Rawdon's and Cecil's cases; in the female the same discovery has been made by vaginal examination by Emmet and by myself, and I have also detected the presence of a stone by vesical examination after dilating the female urethra. 3. Catheterization of the ureters, though easy of application in the female, does not afford satisfactory assistance in these cases, whether done across the bladder through the dilated ureter, or by vaginal cystotomy as practised by Bozemann and Emmet, or by the aid of suprapubic cystotomy. The cystoscope in the cases of anuria is quite unnecessary and can give no information which is not more fully ascertained by rectal or vaginal examination and a sound in the bladder.

If there be a calculus in the terminal part of the ureter it will almost certainly, if of any size, be detected by either rectal or vaginal examination and can be extracted by one of the operations to be mentioned later. But if by these modes of examination nothing is detected in the inferior extremity of the ureter we ought without delay to explore one or both of the kidneys through the loin and to select first the side on which pain or tenderness or swelling or a hard contracted condition of the abdominal walls exists or has recently existed. Through such an incision the kidney and adjacent part of the ureter can be seen and felt and the rest of the ureter catheterised, and if a stone be found it will be possible to remove it, and if no stone be found then by establishing a renal fistula relief will be given to the congested state of the kidney and a condition will thereby be brought about favourable to the resumption of the secretion of urine.

Calculous anuria and uræmia have to be diagnosed from non-obstructive forms of anuria and from other forms of obstructive disease. A case of anuria from double polycystic disease, in which the symptoms and history were those of calculous obstruction, has been under my care lately. Cancer of the uterus after calculus is the most frequent cause of obstructive anuria. Primary cancer of the bladder may obstruct the ureters. Many cases after operations for myoma of the uterus succumb to anuria with dilatation of the ureters and renal pelves. Calculous anuria will be diagnosed from traumatic anuria, in which the vessels of both kidneys are thrombosed by the symptoms following an injury, and from the anuria following catheterisation and other operations on the lower urinary passages by the absence of the general malaise at the onset and of the rigors, high temperature, and intense prostration which accompany urinary fever.

Treatment.—The treatment of anuria up to fifteen years ago was entirely medical. Death was the common result. No wonder; for what else could be expected from purgatives and diuretics, from diaphoretics and anti-spasmodics, from baths, forced exercise, and massage? Drugs, such as digitalis and pilocarpine and others, which induce the elimination of a considerable quantity of water from the system, remove only a small quantity of urea with the water and thus leave the blood proportionately more highly charged with urea. For this reason such supposed remedies ought to be ordered with extreme precaution in obstructive anuria. The surgical treatment of calculous anuria is a question of the day and one of the greatest importance. Formerly no one dared to do more than suggest operation, though Rayer and Gigon in 1856 had strongly recommended it. Nephrotomy should be performed in the gravest cases to prevent death from uræmia; in the slighter and intermittent cases it should be performed to extract a stone which may at any time produce complete persistent anuria. When the calculus is in the lower portion of the ureter or within, or close to, the vesical orifice the advisability of adopting one of the special methods for reaching the ureter in these parts will have to be considered, but in many cases the state of the patient will make it necessary to postpone this for a time at least. Should the obstruction not be removed at the primary operation a lumbar renal fistula should be established and ureterotomy may be subsequently successful, or the stone may be naturally expelled, and thus the normal channel will be opened up and the fistula allowed to close.

Opinions have hitherto differed as to the precise time when the surgeon should interfere. To be successful it is certain that the operation should be done early and before the uræmic stage is reached. But since this stage is generally delayed till after the sixth day some writers have advocated the fifth or sixth day as the period of surgical operation. In Demon's case the intervention was made on the eleventh day and in Chevalier's on the fourteenth with complete success; but on the other hand operations on the third day have been unsuccessful in restoring the secretory function. Moreover, eclampsia necessitating immediate operation may occur as early as the third or fourth day of

[3] Maladies des Reins, tome iii., p. 490.

the anuria, as in Vailhen's case. Sudden death may occur early in an anuric person who seems to be in fair general health. My opinion is that an operation ought to be performed as soon as the anuria is established and the diagnosis is satisfactorily made. We should operate on the side last affected when the indication on this point is clear. It is not the kidney which has longest suffered or which has yielded most calculi which ought to be incised. The contrary ought to be the rule, because the more the kidney is affected the more extreme its degeneration, the less the secretion which it will yield, and consequently the less the benefit from nephrotomy. In the absence of exact history drawn from the patient himself it is necessary to try to ascertain by careful examination of the abdomen which kidney to explore. When there is no enlargement of the kidney and no pain or tenderness there may yet be a considerable degree of hardening from contraction of the abdominal muscles over the kidney which is last involved. In most cases it will be best to explore the kidney first, but in certain exceptional instances, as when the stone can be felt per rectum or per vaginam, or evidence clearly points to the side and precise spot at which it is impacted, ureterotomy should be done. For this nothing less than actually feeling the stone through the abdominal parietes (a most unlikely thing in persons suffering from calculous anuria) ought to satisfy. The localisation of stone, as to whether it be in the kidney or ureter, is very uncertain; most frequently, when impacted in the ureter, the symptoms it causes are referred to the corresponding kidney; but occasionally the reverse obtains and a stone in the renal pelvis gives rise to fixed abiding pain and acute tenderness at one particular spot in the course of the ureter.

The nature of the operation performed in the 49 cases was as follows:—1. Operation stated as nephrotomy or (in a few cases) merely exploration of kidney, in 36 cases. In one of them the operation was performed by the thermo-cautery. 2. Incision of the renal pelvis, 5 cases. One was done by thermo-cautery. 3. Incision of the ureter, 7 cases. One was performed through the rectum. In one additional case an attempt was made to remove an obstruction from the lower end of the ureter by means of the finger in the bladder.

THE TECHNIQUE OF THE OPERATION FOR EXPLORING THE KIDNEY AND URETER.

The method I adopt for exploring the kidney and ureter for stone is the following. The incision I have from the first always employed is a very oblique lumbar one commencing an inch above and in front of the anterior superior iliac spine and continued outwards and backwards to the outer edge of the erector spinæ muscle, about a finger's breadth below the last rib. The length of the incision varies with the figure and degree of stoutness of the individual. More frequently than not it is unnecessary to begin so far forward and sometimes it is advantageous to continue the skin incision backwards a little over the erector spinæ muscle. The direction of the lumbar incision is, however, always in the line between the points mentioned. When more room is required a short vertical or slightly curved incision is made upwards from the oblique wound extending over the back of the twelfth rib. This greatly facilitates deep manipulation and is a step towards clearing the last rib in the event of the excision of that bone being requisite. Manipulation is also sometimes facilitated by snicking the outer edge of the quadratus lumborum. When more room in front is required either for freeing or inspecting the kidney, controlling bleeding in the deep part of the wound, or for tracing the ureter, the incision should be carried in a curvilinear way toward Poupart's ligament and then forward parallel to and an inch above that ligament as far as the internal abdominal ring or further. Bleeding points should be controlled as they occur by pressure forceps, and if the last dorsal or the ilio-hypogastric nerve is in the way it is best to excise an inch or more of it. When freed of its connexions anteriorly, posteriorly, and at both ends the kidney should be brought bodily on to the surface of the loin. This in a large number of persons can be done without difficulty and without causing tension of the renal pedicle, but in others with thick-set trunks and very fat parietes it is not possible to bring the kidney quite out of the body even when great traction is made upon the pedicle. Forcible pulling upon the pedicle, however, must be avoided. When owing to these conditions the kidney cannot be brought out of the wound the wound should be made amply large enough to allow the surgeon to see clearly the kidney which he is about to incise. Unless this be done there is always the risk of wounding the branch of the renal artery or vein which runs over the back of the renal pelvis before entering the parenchyma on the posterior surface of the organ. Moreover, small branches of the renal artery anastomising with the lumbar vessels may be wounded and should be seen to be ligatured. If no calculus is felt an incision is next made into the kidney along its convex border whilst the finger and thumb of the left hand steady the kidney and compress the pedicle. This compression of the pedicle serves a double purpose: (1) it limits hæmorrhage, and (2) it prevents a small calculus which might drop out of one of the calyces from falling into the ureter. Through the wound in the kidney the right index finger is introduced and a careful detailed manipulation is made of every part of the interior of the organ. Needling the kidney for diagnostic purposes is most unreliable and should be abandoned. Whether or not a calculus be found in the kidney the ureter should always be catheterised from end to end to test if its lumen is quite free. If this is not done a small calculus may be missed.

If the ureteral catheter can be passed readily through the renal cavity by way of the incision in the convex border of the kidney this should be done, but it is often impossible or troublesome to hit off the orifice of the ureter in this way. If so, the back of the infundibulum should be cleared and a minute longitudinal incision should be made into it with the point of a narrow sharp scalpel or sharp-pointed scissors, and through this incision the catheter should be conducted. In doing this care must be used not to mistake the renal vein or a branch of the vein for the renal pelvis. Should such an error be made bleeding will be readily controlled by pinching up the edges of the tiny wound and applying a circular ligature. When any doubt arises the vein will be distinguished by watching for the return of blood after compressing it. There is often quite a plexus of fine blood-vessels on the surface of the infundibulum and ureteral wall which must be avoided if possible. If there be a stone in the ureter the catheter will be obstructed at the point of impaction. In the male, whether this point be in the abdominal or the pelvic course of the ureter, the calculus can be reached and removed retroperitoneally by prolonging the anterior or lower end of the incision in the direction mentioned before.

In the female the same procedure answers for the abdominal and first portion of the pelvic course of the ureter, but for the removal of a calculus from the ureter within the broad ligament, especially near the uterus or vagina, the vaginal or sacral route is the best. If situated quite at the vesical orifice of the ureter it can be extracted through the bladder after dilating the urethra and, if needful, slightly incising the ureteral orifice. No attempt should be made to extract a calculus through the bladder unless it be situated quite at the internal opening. A calculus, if it is of fair size, may be felt through the bladder when it is in the ureter just above the point where the duct enters the vesical wall. When here it cannot be so removed without exposing the patient to the danger of an intra-peritoneal urinary fistula. In one of the recorded cases of uretero-lithotomy this accident happened and the patient died. If the ureter is dilated above the stone and the stone can be readily pushed back into the dilated portion this should be done, whether the point of impaction is above or below the brim of the pelvis. The incision in the dilated tube may then be closed by one or two Lembert sutures. Care should be taken to provide drainage for any urine which may extravasate through the ureteral wound, otherwise serious mischief in the pelvic cellular tissue may occur after the too early closure of the external wound. In operating upon the sound kidney I do not hesitate to cut directly down upon a calculus wherever it may present; still less need one do so in a kidney the cavity of which is pouched and the parenchyma atrophied. When so made the incision should preferably radiate from the hilum, but when the parenchyma is very thin and a large branched calculus or several calculi are present the incision may be made in any direction which gives the greatest facility for extracting the stones.

In calculous pyonephrosis I have removed seven stones through as many separate incisions in the thin parenchyma. As long ago as 1829 Gerdy[4] had advised that the convex

[4] P. N. Gerdy: Anatomie des Formes Extérieures du Corps Humain, Paris, 1829. See note on p. 153.

border of the kidney should be selected for incision in nephrotomy. The advantages depending on the anatomical arrangement of the blood-vessels within the kidney of an incision along this border are considerable. Moreover, through no other single incision can a complete examination of the cavity and substance of the kidney be so conveniently made.

After removing a calculus from the renal pelvis, if the convex border has not been incised the interior of the kidney should be palpated either through the opening or if this be too small to admit the finger then by invaginating the infundibulum. When the renal cavity is sacculated and suppurating it should be freely irrigated with a hot weak solution of Condy's fluid, perchloride, or carbolic acid. In a few instances the calyces have been found packed with a putty-like mass of muco-pus, which was thoroughly cleared out with the finger and little swabs of cotton-wool. In every case a drainage-tube is inserted into the wound around the kidney, but not into the kidney cavity itself. I prefer a tube to iodoform gauze, which, by sucking up and retaining the serum and blood, keeps the surfaces of the wound apart and prevents immediate healing. In closing the parietal wound I transfix the whole of the layers, skin, muscles, and fasciæ, with the same sutures carried by means of Hagedorn's large curved needles. I have for some considerable time abandoned the use of buried sutures for the separate layers of muscles and fasciæ. The length of time required for convalescence of course varies. In cases of simple nephrolithotomy patients are often able to sit up on the eleventh or twelfth day with their wounds soundly healed, and many have returned to their homes between the second and third weeks after the operation. Nephrectomy is frequently as rapidly followed by complete recovery. When the kidney and the perinephric tissues are much disorganised healing is apt to take place for the most part by granulations and then four or five weeks are required.

THE MANAGEMENT OF PATIENTS BEFORE AND AFTER LAPAROTOMY.[1]

BY FREDERICK HOLME WIGGIN, M.D.,

VISITING GYNÆCOLOGIST TO THE NEW YORK HOSPITAL; SURGEON TO ST. ELIZABETH'S HOSPITAL; THIRD VICE-PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION, ETC.

IN the early days of the decade now drawing to a close it was generally considered to be a fact that operations within the abdominal cavity could only be performed with a reasonable degree of safety to the patient when undertaken in expensively constructed special rooms attached either to public or private hospitals. But as time has gone on and our knowledge of bacteriology has increased antiseptic surgery has been gradually replaced by aseptic work, and we have found, especially those of us whose fortune it has been to perform operations of the class under consideration in ordinary dwellings, that although the personal effort and responsibility are increased, abdominal operations can be performed with as little, if not less, danger to life in a properly prepared room in the patient's dwelling, as in the best equipped modern hospital. This, coupled with the fact that abdominal wounds are more frequently closed without drainage and therefore allowed to heal under one dressing than was formerly the case, seems to make it evident that the time is not far distant, if indeed it has not already arrived, when patients suffering from abdominal disorders will ordinarily prefer to be operated upon in their own homes rather than to go among strangers in a strange land at this critical time. Hence it will come to pass that the general practitioner in the near future will more often have an important part to play in the management of patients, both before and after the performance of laparotomy, than has hitherto been customary. On this account chiefly the discussion of this important subject has seemed timely, for it is my belief, founded on a considerable experience, that the patient's welfare depends not only upon the technique of the operation itself being properly carried out but also upon the successful management of many so-called minor, and therefore neglected, details both before and after the operation.

[1] A paper read before the Hartford Medical Society and the New York Medico-Surgical Society at their January, 1898, meetings.

Years ago I, then under the pupilage of that great surgeon Professor James R. Wood, learned that the most successful surgeon was he who could best carry out not only the major but the minor details of his work; and this must be my excuse, if one is needed, for the minuteness with which the minor points of routine work are about to be gone into.

Preparation of the patient.—When the condition for which the operation is to be undertaken is chronic, and all the time desired can be had for the preparation of the patient for the ordeal which he is to undergo, much can be done which will not only diminish the risk about to be incurred by him but which will ultimately hasten convalescence. In such a case it is for the patient's welfare that the hospital where the operation is to be performed should be reached, or the trained nurse employed if the patient is to remain at home, at least one week prior to the date fixed upon for the operation. This allows the individual to become accustomed to the attendants or the environment, which is of undoubted importance, as it tends to lessen the dread and nervous tension, both of which are great in such a crisis even under the best of circumstances. During this week the sufferer should be encouraged to spend the greater part of the time in bed for the purpose of getting thoroughly rested, as patients too often come under operation physically exhausted. During this period massage may be employed to advantage in lieu of physical exertion as it improves the circulation, promotes digestion and the general bodily welfare. As far as is compatible with a healthy mental condition, visitors and friends should be excluded. A daily record of the patient's bodily temperature, pulse, and respirations should be kept. An examination of the heart and lungs and a final analysis of the urine should be made at this time. As it is of great importance that the intestinal canal should be thoroughly collapsed at the time of operation, careful attention should be paid to unloading and emptying the bowels as well as to getting the digestive organs in good working order. This is best accomplished by giving early in the week several small doses of calomel and soda daily for three days. There are to be followed each morning by a saline, and this, in turn, on each of three succeeding mornings by a large enema, unless contra-indicated (3 to 4 quarts of saline solution, 1 drachm to the quart). The rectum should be finally washed out with a pint of the same solution six hours before the performance of the operation. The large enema just alluded to is best given with the patient lying on the left side, a fountain syringe being used for this purpose the reservoir of which should not be elevated more than 3 ft. above the patient's body. A bulb syringe should not be used for this purpose, for in the first place it injects the fluid irregularly and with too much force and consequently only a small quantity can be employed; in the second place it is apt, if carelessly used, to permit the entrance of air into the bowel. An extreme instance of this sort came under my observation some years since. A nurse having been directed to give a patient an enema undertook to force fluid contained in a pitcher into the gut by means of a bulb syringe. She worked away vigorously for a time, directing all her attention to the patient, who complained bitterly, but she failed to notice until it was too late that the distal extremity of the tube had escaped from the liquid and the patient's abdomen was greatly over-distended. The family physician was hastily summoned and with some difficulty relieved the patient from a very severe attack of wind colic. The water for the enema should have a temperature of 100° F., and should be introduced into the canal slowly, being frequently intermitted as the patient complains of a feeling of distension or of intestinal colic. Both of these sensations pass off with the cessation of the flow and by persevering in this way three or four quarts of saline solution can usually be introduced into the colon in the course of half an hour with but slight discomfort to the patient. The patient should be encouraged to retain the fluid for another fifteen minutes before it is allowed to escape. The administration of these enemata should be supervised by the physician, as the nurse seldom knows how to accomplish the introduction of the desired quantity of fluid into the intestinal tract, or if she has the knowledge and experience she has not sufficient authority over the patient to effect the desired result. I have often been told by nurses entrusted with this duty that they have given the enema of four quarts not as ordered but in divided doses, thinking probably that as "twice two equals four" they had performed their duty in a satisfactory manner. It is this misunderstanding that so often causes the

patient's bowels to act on the operating table, not only to the great discomfort of the surgeon and his assistants, but frequently, when the operation is about the vagina, endangering the patient's life.

The course indicated for cleaning and emptying the intestinal tract has proved in my experience to be a much more satisfactory one than that generally employed—i.e., the administration of a single large dose of calomel the evening previous to the day set for the operation and followed in the morning by a saline and a small enema. The latter method usually fails to properly empty the colon, but succeeds, as has been already said, in causing several movements after the patient has been placed under the anæsthetic and on the operating-table.

The patient's diet during this week of preparation should be of an easily digestible nature, and he should be encouraged to partake freely of fluids for the purpose of restoring the normal quantity of fluid in the body. If needed cardiac stimulants should also be given. Hot baths (110°) of ten minutes' duration should be given daily, not only for cleansing purposes but to promote the secretions of the skin and kidneys. Special attention should be paid to the navel and pubic region, which should, if practicable, be shaved on the day previous to that fixed upon for the operation, otherwise it must be done after the patient has been placed under the anæsthetic. If the individual is a female the time of the operation should be, when possible, arranged for a date a few days after the cessation of the menstrual flow and a vaginal douche should be given consisting of boric acid and followed by one of formalin (½ per cent.) or of bichloride, 1 to 4000. It is well during these days preceding the operation to give the patient a mild hypnotic every other night. I have found a combination of sulfonal and chloralamid to answer the purpose. This hypnotic should be always given on the last night of the period under consideration.

The patient's skin covering the abdomen should be prepared for the surgeon by thoroughly cleansing it, applying a soap poultice for two hours over the site of the proposed incision and then replacing it by a compress moistened in weak bichloride solution. This compress is allowed to remain until the patient is placed on the operating table. These final preparations can be made the evening before if the operation is to be performed at an early hour in the morning or in the morning if an afternoon hour has been decided upon. It is wise to fix upon as early an hour of the day as practicable, as the patient in this case has less time in which to become exhausted from want of food or restless or nervous from the dread of what is to come. It is of great importance that once the hour has been determined there should be no postponement, as I have seen patients almost collapse under the extra nervous strain entailed by half an hour's delay.

If the operation is to be performed at an early morning hour—i.e., 8 A.M.—the patient should be given a peptonised milk punch at 11 o'clock the previous evening, and if he awakens at 5 or 6 A.M. 1 oz. of liquid beef peptonoids may be given, but nothing more. It has been my experience that a small amount (1 oz.) of stimulating and concentrated food administered about two hours prior to the taking of the anæsthetic diminishes the liability to heart failure and also lessens the nausea and vomiting which frequently follow the return to consciousness. If an afternoon hour has been decided upon another peptonised milk punch may be given the patient when he awakes and 1 oz. of liquid beef peptonoids at 11 A.M. If the case is of an acute character and an immediate operation is demanded little more can be done than to cleanse the skin in the manner already described and douching out the vagina if the patient is a female. A stimulant should be administered if the pulse is feeble or if the patient is suffering from collapse due to intestinal perforation. In this condition if the patient does not respond to the stimulants the operation should not be performed as it will prove of no avail. If, on the other hand, the patient rallies the operation should be done with as little delay as is practicable, but even in those cases it should not be forgotten, as Dr. Abbé has pointed out, that if we would have our work come to a successful issue we must have good light, good assistants, and proper facilities for intra-abdominal irrigation.

If the operation is to be performed in a private residence, a room with a north light should be preferably selected. Its furniture should be removed at least twenty-four hours before the room is to be used. After it has been thoroughly cleansed, the windows should be left wide open for two or three hours, then closed, and the woodwork wiped over with bichloride solution, 1 to 1000. The floor should be liberally sprinkled with a similar solution. A table, 20 in. wide by 30 in. high, and varying in length according to circumstances, will be needed, as well as several smaller tables or stands, a few wooden-bottomed chairs, several large pitchers, four or five basins, several meat-platters, and a receptacle (a fish-kettle) for sterilising the surgeon's instruments. All these articles should be cleaned and washed over with bichloride solution before being placed in the operating-room. The room should be closed after all the articles have been placed in it, and should remain so until needed. A dozen towels, sterilised by boiling or by steaming in a steriliser, and several gallons of cold and hot water, sterilised by boiling, complete the arrangements to be made before the arrival of the surgeon, who usually provides instruments, ligatures, suture materials, and dressings. For emergency operations it is best to make no attempt to clean the room, but the floor should be covered with a sheet wet with bichloride solution. This avoids vitiating the air of the room with dust—a thing greatly dreaded by the surgeon.

The patient should be so clad for the operation as to reduce to a minimum the bodily exposure. The clothing should consist of a warm undershirt, drawers and stockings, the two last-named often being made in one piece. The anæsthetic should be administered to the patient before he is brought into the operating-room. If the anæsthetic to be employed is ether it is advisable to administer hypodermically ¼ gr. of morphia and $\frac{1}{150}$ gr. of atropia, half an hour before the induction of the narcosis, as this tends to diminish bronchial secretion and materially lessens the amount of ether to be given. If, for the administration of the ether, a closed inhaler is used of the Clover type, and the gauze contents are saturated with the fluid at the start, and the mouthpiece is rapidly brought down over the patient's nose and chin, so as to exclude the air, the anæsthetic state will be quickly induced, and there will seldom be a stage of excitement. It is a fact that patients can be rendered unconscious and kept in this condition for an hour with only 4 oz. of ether, and for the second hour with only 2 oz. additional. After the patient has been placed under the influence of the anæsthetic agent and put upon the operating table, on which sterilised blankets have been placed in such a manner as to admit of their being folded over the patient's chest and lower limbs, leaving only the abdomen exposed, the bichloride compress previously alluded to is removed and the skin is finally scrubbed with hot water and tincture of green soap. The pubic region should receive special attention. This scrubbing is to be followed by irrigation with sterilised water, ether, and alcohol. If the patient is a female it should be the rule to cleanse the vagina in the same manner, but instead of scrubbing the tissues with a brush it is better to use a piece of gauze held in the jaws of a sponge-holder as the brush tends to excoriate the tissues and thereby increases the danger of septic infection.

While the technique of abdominal operations is not within the scope of this paper I ask leave to say that for a long time past I have been in the habit of entering the abdominal cavity by means of an incision through either the left or right rectus muscle as the case required, the muscle being simply split and not divided. This incision heals readily and there appears to be little danger of ventral hernia provided the edges of the fascia are approximated. The appendix can be readily reached and removed through the incision over the right rectus muscle. Not long since I removed the greater portion of a long and adherent appendix through an incision made over the left rectus muscle for the purpose of removing the left ovary. Of course this last incision is not recommended for the removal of the appendix. Before closing the wound in the abdominal wall it has been my custom in most instances, notably in those cases where the formation of adhesions between the viscera was undesirable, to leave behind in the general cavity a considerable quantity of so-called normal salt solution (½ a drachm to the pint) at a temperature of 110°, after irrigating the cavity freely with the same solution. This not only, in my opinion, tends to prevent the formation of intestinal adhesions, but also serves to stimulate the patient, who generally leaves the table in good condition and with a warm, moist skin. The edges of the wound are approximated by means of a single row of silkworm gut sutures which pass through all the

different layers of tissues. I have gradually learned that these deep sutures should be placed at least 1 in. apart and loosely tied so as to allow for the swelling of the parts, which is considerable and varies in amount with the thickness of the wall. The interference with the circulation by means of these deep sutures when placed too closely together and tied so as to approximate the edges of the skin accurately is, I believe, a more frequent cause of stitch abscess than is infection. After the deep sutures have been tied, as indicated, the edges of the skin should be accurately adjusted by means of a buried running suture of silkworm gut or by a continuous suture of catgut. While the operation is progressing the anæsthetiser, who should be an experienced physician, should watch the patient constantly and pay no attention to the operator. As soon as the reflexes have disappeared he should raise the inhaler from the patient's face to replace it as soon as they return. In this way the patient inhales the minimum amount of ether and carbonic acid gas. As soon as the pulse increases twenty or thirty beats a minute a stimulating hypodermic injection of strychnia should be administered and repeated as needed from time to time until $\frac{1}{\overline{30}}$ gr. has been given. To this may be added $\frac{1}{100}$ gr. of nitroglycerine every fifteen minutes. If in spite of these stimulating injections the pulse exceeds 150 beats per minute it is well to open either the right or left median cephalic vein and introduce into the circulation one to two pints of saline solution at 100°. This solution should be made ready in advance. For giving such an injection a simple apparatus, consisting of a rubber tube with a funnel at one end and a blunt hollow needle at the other, is all that is requisite.

After-treatment.—The operation having been completed, the wound dusted over with acetanilide powder, and the usual dressings applied, the patient should be returned to his bed, being placed directly within the folds of a blanket and surrounded, if necessary, with hot water bags or bottles. Care should be taken lest they be overheated and so blister the still partially unconscious patient. This warning is given because it is not at all uncommon, when the matter is left entirely to the nurse, for the patient to receive one or more severe burns from this cause. When a quantity of hot saline solution, already alluded to, is allowed to remain in the abdominal cavity, the patient generally leaves the operating table in good condition and with a warm, moist skin. If the patient's pulse is weak and rapid it is wise to raise the foot of the bed somewhat and soon after consciousness has been fully regained to administer $\frac{1}{4}$ gr. of morphia and $\frac{1}{100}$ gr. of atropia to quiet the patient and combat shock. There is, however, usually very little shock unless there has been much blood lost during the operation. After this one dose the use of morphia should be discontinued, as it deranges the digestive system and obscures the various symptoms. It is not necessary to keep the patient in one position during the first three or four days. In a recent hospital case this was well demonstrated by the fact that although the patient fell out of bed the night following the operation convalescence was smooth and uneventful.

During the first twelve or eighteen hours following the operation the patient should not be allowed anything by the mouth except a little warm water from time to time. If ether has been administered intelligently in small quantities and in the manner previously described there will generally be little or no vomiting or nausea and when it does occur it can be overcome by the external application of chloroform to the epigastrium. If the demand for fluids is urgent, which is seldom the case where the saline solution is left in the general cavity, it is due to gastric irritation and can usually be successfully combated by two or three large doses of subnitrate of bismuth. The patient should during these early hours of convalescence be stimulated and nourished, if necessary, by means of enemata, unless the operation has involved the breaking up of extensive and firm adhesions in the pelvic cavity, in which case a weak place in the bowel may be ruptured and the enema and fæcal contents of the lower bowel be forced into the general peritoneal cavity. This accident has occurred twice in the past two years in my practice. After the passing of the first twelve or eighteen hours, if the patient is not suffering from nausea or vomiting and the pulse-rate is much the same as before the operation, a drachm of liquid beef peptonoids or of some other similar preparation may be given and repeated, if well borne, every twenty minutes until four doses have been taken, when, after an interval of two hours, a small quantity of equal parts of milk and lime-water or of peptonised milk may be given from time to time until 4 oz. have been taken. After this there should be an interval of two hours, and then $\frac{1}{2}$ oz. of liquid beef peptonoids may be administered. After another interval of two hours 4 oz. of peptonised milk may again be given. The quantity of milk should be gradually increased and the interval lengthened until the patient takes 8 oz., or its equivalent, every three hours, but once during the twenty-four hours the interval should be lengthened to six hours. The general tendency is to give too small quantities of nourishment at too frequent intervals, which fatigues the stomach and is apt to cause irritability of this organ and to engender a disgust for food. During the interval, if the patient desires more liquid, egg-albumen and water (the whites of three eggs to a pint of water to which a little salt has been added) may be allowed him frequently. During the first forty-eight hours following the operation, if the patient is disturbed by reason of intestinal gas, great relief is often afforded by the introduction through the sphincter ani of a short rectal tube, or even the nozzle of a fountain syringe. Some time since I performed a laparotomy upon an out-of-town patient and left her the following morning in the care of her physician, whose experience in abdominal cases after operation was limited. A few hours later the woman began to complain of severe abdominal pains and distension. The medical man was summoned and after examination he diagnosed the condition as symptomatic of peritonitis. Fortunately, instead of giving morphia, a brother physician who had had more experience in the care of such cases was called in. After examining the patient the latter inserted the rectal tube of a fountain syringe into the bowel and was rewarded by a rush of escaping gas. The abdominal distension and pain quickly disappeared, and in thirty minutes from the time the tube was introduced the patient was sleeping quietly. If this simple procedure proves inadequate friction may be applied over and along the colon, as has been recently mentioned by Dr. A. E. Gallant. This complication, however, will seldom arise if during the week preceding the operation proper attention is paid to clearing out the intestinal contents. If the patient continues to do well and retains nourishment and the intestinal canal has been well emptied no cathartic need be administered until the third or fourth day when $\frac{1}{10}$ gr. of calomel and 1 gr. of soda should be given every half hour for five hours. If the bowels do not act within three hours after all the calomel has been taken a seidlitz powder should be administered and repeated after another interval of three hours. After the bowels have moved, if all has gone well, the pulse-rate will be much as it was prior to the operation, and by the evening of the fourth day the body temperature should be normal, in which case the patient may be rapidly allowed to resume ordinary diet.

The dressings should be removed on the fifth day, and if the sutures are beginning to cut the tissues they should be removed and the wound supported by strips of adhesive plaster; otherwise they should be allowed to remain a few days longer. The dressings having been removed the wound should be washed with hydrozone and bichloride solution and freshly dusted with acetanilide powder before they are replaced. Before the sutures are removed the wound and its surroundings should be thoroughly cleansed. A suture is then picked up at one side by means of a pair of thumb forceps and the skin at the angle is depressed by the flat surface of a pair of scissors, the blades of which straddle the strand of gut, which is then cut through. The object of this manœuvre is to cut the portion of suture which has been buried in the tissues and which is therefore clean, so that in dragging the gut through the deeper tissues and the peritoneal cavity the danger of infection will be reduced to a minimum. The patient should remain in bed for about eighteen days, and may then be allowed to sit up and soon thereafter to walk about and resume his ordinary occupation.

Complications.—The complications which may be encountered during the period of convalescence and which change this ordinarily peaceful period into a more or less stormy and anxious one for both the patient and the physician, taxing the latter's ability to the utmost, occur in the following order: concealed hæmorrhage, peritonitis, intestinal paresis, intestinal obstruction and stitch abscesses.

The occurrence of concealed hæmorrhage, which fortunately at present seldom happens, especially when the vessels are tied with catgut taken directly from alcohol in which it is preserved, manifests itself during the first

twenty-four hours by a rapidly rising pulse, decreased in volume, and accompanied by a falling body temperature, dilatation of the pupils, and a clammy perspiration. When this condition is followed by a rapid rise of body temperature to 103° F. or over, dissolution is imminent. As soon as this complication is recognised an intravenous injection of saline solution should be given and the patient should be stimulated by hypodermic injections of ether, whisky, strychnia, or digitalis, and if there is a reasonable response the abdomen should be at once opened and the bleeding point searched for and secured; otherwise the operation would prove useless and would only be an ante-mortem instead of a post-mortem examination. The decision as to the occurrence of hæmorrhage and the necessity of reopening the peritoneal cavity should be made with great deliberation, as the unnecessary performance of this operation may seriously endanger the life of the patient.

The onset of peritonitis is indicated by a gradual but persistent rise of pulse beginning on the second or third day, intestinal distension, and rigidity of the abdominal muscles, whether accompanied by elevation of body temperature or not. If the pulse-rate rises and remains in spite of our efforts above 120 per minute the outlook is generally unfavourable. As soon as this tendency of the pulse to increase in frequency after the first day is recognised an effort should be made to move the bowels by the administration of calomel followed by a saline. If this does not act in a reasonable time another dose of calomel should be given, followed after an interval of several hours by another saline. A stimulating enema of 7 oz. of a saturated solution of sulphate of magnesia and one ounce of glycerine is often very effective. If the bowels act freely the patient is generally safe, but if the symptoms persist instead of subsiding the stitches should be removed from the abdominal wound, the cavity freely irrigated and its contents cleansed in the manner recommended by Finney.

The advent of intestinal paresis is marked on the second or third day by distension of the abdomen and the occurrence of more or less persistent vomiting, the contents of the stomach being ejected without nausea and the fluid being at first of a yellowish and later of a brownish colour, but not having a fæcal odour. As the colour of this fluid darkens the prognosis becomes less and less favourable. It is well to bear in mind that vomiting resulting from the administration of the anæsthetic subsides usually during the first twenty-four hours, but that it may follow the administration of morphia. When the diagnosis of intestinal paresis has been made the stomach should be washed out and salines given at frequent intervals until the bowels act, even if the saline be partially ejected by the patient. My efforts have been crowned with success in more than one instance by the persistent administration of salines after the patient's condition had seemed hopeless. The stimulating enema already alluded to should be given and friction should be applied over the colon. If the bowels act the patient usually has no further trouble.

Intestinal obstruction, which fortunately has seldom or never occurred in those cases in which the writer has left saline solution in the general cavity, is differentiated from intestinal paresis by the pain over the site of the obstruction and more persistent vomiting accompanied by nausea, the vomited matter having sooner or later a fæcal odour. This condition should be treated as soon as recognised by re-opening the abdominal cavity and finding and freeing the constricted portion of gut.

Stitch abscesses usually announce themselves by the occurrence of a rise of body temperature towards the close of the fourth or fifth day and should be treated by the application of hydrozone and the removal of the sutures. The opening in the skin should, if necessary, be enlarged to allow of the free evacuation of the pus.

While the various symptoms described have individually to be considered and their meaning weighed they also have to be considered collectively and in judging of the gravity of the patient's condition the facial expression is of great value to those who have had experience. A depressed and anxious countenance generally denotes a grave condition, while a cheerful one, even if accompanied by an elevation of pulse and temperature, indicates that the condition is not serious. The physician charged with the care of a patient upon whom a laparotomy has been performed should not think too constantly of peritonitis—that bugbear of all who have had little experience with abdominal work—and consequently feed the patient upon salines rather than with milk or soup. On more than one occasion the writer has known this fear to be the father of the thought, and either the patient's life to be sacrificed or convalescence to be needlessly prolonged by this error in judgment.

In closing this paper, it is my desire to again call attention to the points which I think of importance, and which, as they are considered minor ones, are often overlooked. They are as follows:—1. The importance, whenever practicable, of prolonged preparatory treatment of patients about to undergo an abdominal operation. 2. The importance of the administration of cathartics in the early part of this period, followed by large enemas for the purpose of cleansing the intestinal tract. 3. The importance of keeping a record of the body temperature, respirations, and pulse-rate for several days in advance of the operation and of making a final examination of the urine. 4. The necessity, in the female, of arranging to have the operation performed a few days after the menstrual period and the cleansing of the vagina even when it is intended that the operation shall be by the abdominal route only. 5. The administration of a small quantity of peptonised food (1 oz.) containing stimulants two hours before giving the anæsthetic for the purpose of lessening the tendency to nausea and vomiting after the recovery of consciousness. 6. The necessity of the anæsthetic being given by an experienced physician and in the smallest possible quantity. 7. The necessity of protecting the patient's body properly with clothing and blankets during the operation. 8. The advantage of stimulating the patient before the heart has become much exhausted and of using intravenous saline injections before the radial pulse has become extinct. 9. The leaving in the abdominal cavity after free irrigation of a quantity of hot saline solution for the purpose of stimulating the patient, preventing (?) the formation of intestinal adhesions, and lessening the danger of septic infection of the peritoneum. 10. The necessity of making the patient comfortable by change of position during the first two days of convalescence and by the use of the rectal tube. 11. The necessity for the early administration of food in reasonable quantities and at proper intervals. 12. The necessity of withholding stimulating enemata after operations in which extensive and firm pelvic adhesions have been broken up. 13. The necessity for deliberation as to the wisdom of re-opening the peritoneal cavity in a given case of supposed concealed hæmorrhage. 14. The importance of washing out the stomach as soon as the diagnosis of intestinal paresis is made and of the persistent use of saline cathartics till the bowels move. 15 The importance of not administering cathartics too early or in too large doses to those convalescing from abdominal operations and who are pursuing a normal course.

New York.

A CASE OF ICTERUS GRAVIS.

BY EDWARD O. DALY, M.D. OXON.,
PHYSICIAN TO THE HULL ROYAL INFIRMARY.

UNDER the term "icterus gravis" cases of jaundice occasionally occur, either in endemic or epidemic form, which usually prove very rapidly fatal. These cases closely resemble those of acute yellow atrophy and are therefore probably due to a very similar poison.

A woman, aged twenty-six years, married five years, the mother of two children, had not been in good health for some months. The catamenia had been irregular and pain had been complained of both in body and limbs from time to time since her last confinement in 1894. On Feb. 7th last she appeared to be in her usual health but the next morning, although not feeling well, she kept an appointment at her dressmaker's, when she was attacked with faintness, shivering, and vomiting. After her return home she vomited several times and the bowels acted freely once. Dr. Coates of Patrington (her usual medical attendant) saw her in the evening and ascertaining that there had been some uterine hæmorrhage (after two or three months' amenorrhœa), and finding some enlargement of the uterus, thought a miscarriage was threatening. He visited her again the next day (Feb. 9th) at noon and finding her flushed, with congested conjunctivæ, a temperature of 102° F., and a pulse of 120, and hearing that she had vomited several times during the night, he suggested

a consultation. Mr. Howlett saw her about 1.30 P.M. During that short interval a great change for the worse had taken place. The whole surface of the body and conjunctivæ had become deeply jaundiced and she had passed into a "typhoid condition." When I saw the patient for the first time at 5 P.M. she seemed hardly conscious, the skin was hot and dry, and the colour was very dark. The temperature was 102°, the pulse was 130, and the respirations were 24. The pupils were dilated but equal. The cardiac and respiratory sounds were normal; the tongue was dry and brown. Hepatic dulness was increased slightly. Apparently there was some tenderness in the splenic region but no definite enlargement. No urine had been passed since the evening before. As both Dr. Coates and Mr. Howlett had found the uterus enlarged it was decided to dilate and examine its interior. Nothing, however, was found, nor were any signs of recent abortion discovered. The catheter drew off about an ounce of black thick fluid. An enema of soap-and-water was quickly returned and it presented a dark black colour; this and some dark green matter vomited shortly after the uterine examination and the fluid drawn off from the bladder were sent up to the Clinical Research Association. On the morning of Feb. 10th at 9 A.M. the patient was restless and unconscious. The skin was deeply jaundiced. There was complete suppression of urine. There was no diminution in liver dulness. The abdomen was not distended. The temperature was 100°, the pulse was 130, and the respirations were 30. The bowels had not acted. Examination of the blood showed some increase of the white cells. After a wet pack the patient freely perspired and seemed temporarily better. During the evening of the 10th the pulse and respiration gradually increased in frequency though the temperature was found to be subnormal, the abdomen became distended, and total suppression of urine continued. The liver dulness did not appear to be altered. The patient never regained consciousness and died at 11 A.M. on the 11th.

The report received from the Clinical Research Association threw no light on the case. Phosphorus was certainly absent from the vomited matter and from the fluid from the bowel, and by no method could leucin and tyrosin be separated from the urine, though the quantity of urine was very small for the purpose. No mineral poison of any kind could be found in any of the specimens.

Remarks.—Jaundice with cerebral symptoms occurs (1) in phosphorus poisoning; (2) in typhus, yellow, and relapsing fevers and in pneumonia; (3) in pyæmic abscesses of the liver; and (4) in acute yellow atrophy, in Weil's disease, and in other severe cases of icterus gravis. Poisoning by phosphorus can hardly be distinguished from acute yellow atrophy unless the patient owns to having taken the drug or unless some of it is found in the vomited matter or fæces. None could be discovered and there was not the slightest reason to suspect that any had been taken either intentionally or otherwise. There was no evidence that the patient was suffering from any of the acute specific diseases, so that the diagnosis seemed to rest between acute yellow atrophy or icterus gravis and pyæmic abscesses of the liver. Pyæmic abscesses of the liver seemed contra-indicated (1) by the absence of any cause, external or internal, likely to induce them; (2) by the absence of rigors and profuse perspirations throughout the illness; and (3) by the very sudden supervention of intense jaundice. By a process of elimination the diagnosis of acute yellow atrophy or some other closely allied condition was arrived at. The points against acute yellow atrophy were: 1. Absence of diminution in the hepatic dulness. In order to establish the diagnosis of acute yellow atrophy we should observe a rapid diminution in the size of the liver. Even in the bodies of patients who have died four days after the commencement of symptoms the liver has been found much reduced. 2. Neither leucin nor tyrosin was found in the urine, but the quantity of urine obtainable was very small. 3 Complete suppression of urine. Although as a rule the urine undergoes important changes its quantity is not materially altered. Changes similar to those found in the liver have been noted as occurring in the kidneys, but I have not been able to find any case of acute yellow atrophy reported where total suppression of urine was present. As unfortunately no post-mortem examination was allowed the exact condition of the liver and kidneys must remain doubtful.

Hull.

THE OPERATION OF GASTRORRHAPHY (GASTROPLICATION), WITH NOTES OF A CASE.[1]

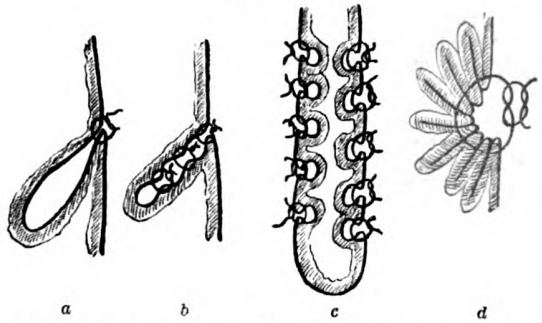
BY BERKELEY G. A. MOYNIHAN, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON, LEEDS GENERAL INFIRMARY; DEMONSTRATOR OF ANATOMY, YORKSHIRE COLLEGE.

GASTRORRHAPHY or "gastroplication" is an operation which has been designed for the treatment of dilated stomach not depending upon any obvious or removeable cause in or around the pylorus or duodenum. The postulate upon which the claim of the operation is based is that there are certain cases of dilatation of the stomach, of the "atonic" variety, where the grave and distressing symptoms depend very largely, if not solely, upon the enormous physical bulk of the organ. In such cases the operation by reducing the mass of the stomach and by lessening its cubic capacity would afford a reasonable prospect and probability of an abatement or a complete recession of all the disabilities due merely to such enlargement. It is an operation which consists, not in the removal or resection of any part of the stomach, but merely of the folding in, and subsequent fixing, of the anterior wall, or part of it, or of portions of both anterior and posterior walls. Various methods of carrying out this idea have been suggested and these I propose briefly to enumerate and describe later. I have recently had under my care a patient upon whom I have performed gastrorrhaphy with very signal relief to his symptoms and, although the time which has elapsed since the operation is altogether too short for me to give an idea as to his future immunity from suffering, I think a useful purpose may be served by my giving some details now of his history, treatment, and present condition.

A man, aged forty-seven years, was sent to me by Mr. Metcalfe Sharpe of Farnley on Aug. 16th, 1897, with the following history. During the last five or six years he had suffered from "indigestion" and occasional vomiting. For an hour or more after a meal he would feel comparatively tranquil and comfortable, but at the end of that time a feeling of weight and oppression in the epigastrium gradually developed until the pain became acute and at times wearing and intolerable from its mere persistence. His mouth was parched, his tongue was dry, harsh, and hot, and his thirst was almost unquenchable. During the period of distress there was occasional eructation. Vomiting, which latterly had been self-induced, was always followed by considerable relief, and he volunteered the information that at the early onset of this symptom fragments of food partaken of some few days before had returned in the vomit. Medical treatment both at the Leeds Infirmary and elsewhere had been for some time continuous and unremitting. Every drug with any sort of action on the stomach, every artificial aid to digestion known to science, and almost all the intestinal antiseptics seem to have been tried upon him, with at times occasional benefit, but latterly he had lost his faith in the medicine bottle and had abandoned drugs entirely. At the infirmary, where he was labelled "Dilated Stomach," he was taught to practise lavage of the stomach with very great temporary benefit. The washing out relieved him so much that for the last six months he had employed it twice daily. Large quantities of water were used on each occasion and he had roughly calculated that the stomach would hold five quarts. That his apparently exggerated reckoning was fairly accurate I feel sure, as on one occasion he had vomited a measured three quarts and his stomach was still splashy. Even by this careful attention to his stomach, however, he was never for very long quite free from pain, uneasiness or oppression, and he was anxious to know if anything further could be done for him. There was no history of jaundice or of hæmatemesis.

On examining him he was seen to be a thin, shrunken, sallow-complexioned man, wasted, nervous and ill. On uncovering the abdomen I found the stomach to be enormously dilated and I roughly computed that it would fill about two fifths of the whole abdominal cavity. At the pylorus I could feel nothing abnormal—no tumour, no special tenderness, and no rigidity of muscle. I could not elicit any obvious



[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society, January, 1898.

peristaltic contraction of the stomach wall. I suggested to him an exploratory abdominal operation. If any pyloric disease were found it was to be appropriately dealt with by removal, by separation of adhesions or by gastro-enterostomy. If I found only a dilated stomach with no perceptible cause I was to perform gastrorrhaphy. He very willingly consented and on Aug. 31st I operated in the manner I shall presently describe, having negatived so far as I was able the presence of any obstructive condition in the region of the pylorus. His recovery from the operation was rapid. I think I never saw a patient suffer less from the usual post-operative troubles. He had none of the common drawbacks incident to almost all abdominal operations, no vomiting, no headache, and no thirst. From the very first I allowed him fluid by the mouth in small but gradually increasing qualities. He expressed immediate and complete relief from all his symptoms, but I attributed this as much to his lessened diet and recumbent position as to any immediate benefit attributable to the operation. He was kept in bed for a fortnight and was then allowed to get up and go home. His improvement has been uninterruptedly maintained. All sense of gastric uneasiness has left him. He has vomited once only and this seizure he ascribed to a specific and not improbable cause. He has gained slightly in weight. Before the operation he was 8 st. 1 lb.; now he weighs 8 st. 11½ lb. His food is varied much more than at any time during the last five years and his dietary is fairly liberal. He is amply satisfied with the result of his treatment and only wishes he had undergone the operation a year or two sooner. It is, of course, too early to speak of a cure in this case, but the patient has at least had four and a half months of such enjoyment of life as he had thought impossible and the hopes of which he had long ago abandoned, and I see no reason why this improvement should not be still longer maintained. His stomach is now on percussion a shade larger than a normal stomach, but it has undergone no increase since the first examination I made at the conclusion of the operation.[2]

I will now speak of the operation itself. It is to a Swiss surgeon, Bircher of Aarau, that the credit of having first performed the operation, which was forecast by Ewald, belongs[3]; his first three cases were published in 1890. He was followed by Weir of New York in 1892,[4] by Brandt of Klausenburg in 1892,[5] by Bennett of London,[6] and by Shattuck of Boston in 1896.[7] The method of carrying out the principle of the operation seems to have differed with each operator and I shall show by means of diagrams what particular procedure was employed by each of the surgeons I have named.

In Bircher's method (Fig. 1, *a*), which was adopted by

FIG. 1.

a *b* *c* *d*

a, Bircher's method—vertical section of the stomach. *b*, Weir's method—vertical section of the stomach. *c*, Brandt's method—five parallel folds are shown, but Brandt himself only made two. *d*, Method adopted by myself.

Shattuck, the operator used a series of sutures, thirty-five in number, which at one end passed through the serous and muscular coats of the stomach at the greater curvature and at the other end picked up a similar portion of the stomach wall at the lesser curvature. On tying these stitches almost the whole of the anterior wall of the stomach was doubled upon itself and formed a wide fold projecting into the interior of the cavity. The introduction of the sutures was facilitated by passing the end sutures first and holding the stomach up by means of them. A pair of heavy forceps laid on the anterior wall of the stomach made the infolding easier. When the stitches were tied the surfaces brought into accurate and close apposition were not more than ½ in. in breadth and would be therefore not unlikely to be torn asunder if any great tension were put upon the adhesions.

The disadvantage in Bircher's operation just alluded to was recognised by Weir of New York, who describes his operation (Fig. 1, *b*) as follows: "In the centre of the space between the upper and lower borders of the stomach a dimpling in of the gastric wall was made, first, by the pressure of a sound to a depth of 1 in. A row of eight or ten interrupted silk sutures was now made, passing through the serous and muscular coats for a distance of from 6 in. to 8 in., and the sound was then withdrawn. A second series of sutures about 1 in. from the first was again made, dimpling in an additional portion of the stomach wall and in a similar manner. A third and fourth row were applied until through a distance of some 4 in. or 5 in. the greater curvature was applied to the lesser. When the row was completed a double fold of the stomach equal to the breadth of the hand and nearly its length was formed." This method is, I think, a very decided improvement upon Bircher's, but the introduction of the sutures is more tedious and the time spent is considerably longer.

The next operator was Professor Brandt of Klausenburg (Fig. 1, *c*), who, operating in 1894, makes the statement that he had planned and demonstrated his operation, which he terms "gastroplication," in 1889. His method consisted in the introduction of sutures both on the anterior and posterior walls in such manner that two or more parallel folds were formed on each surface, one reef being taken in above the other. In this operation 200 stitches were introduced. This operation is more complicated than is desirable. To get to the posterior wall of the stomach and to make two parallel folds in it by means of 100 stitches is by no means an easy matter. The operation is necessarily more prolonged and when completed has no advantages which I know of as compared with other methods.

In 1896 a paper was published in THE LANCET by Dr. Ewart and Mr. Bennett of St. George's Hospital. Mr. Bennett, not knowing that the idea of diminishing the size of the stomach had been previously carried out, performed an operation very like Bircher's, but did not infold the whole of the anterior wall. The fold in his case was about 3 in. deep and 12 in. in length. It was intended to take in a second reef at the greater curvature, but the condition of the patient was very unsatisfactory, and the project had to be abandoned. Mr. Bennett's patient when seen seven months after the operation had some symptoms pointing to a recurrence, and it was suggested that the narrow line of adhesions might be giving way as a result of the constant dragging upon it. Mr. Bennett therefore proposed in any subsequent operation which he might perform to pass the sutures in and out through the stomach wall twice or thrice, so that, on tying, larger surfaces of the serous covering of the stomach would be apposed. The method which I adopted in my case was a carrying out of this suggestion of Mr. Bennett. I passed twelve sutures at a distance of about 1 in. from each other and each suture picked up the stomach wall at nine points. (Fig. 2.) The sutures were made to radiate from the lesser to the greater curvature and included all the anterior part of the stomach wall except for a small area at the pyloric and cardiac extremities. The sutures were drawn upon, held up and tied one by one. It was then seen that there were slight bulgings at each end of the reef which had been made and a second and third series of sutures were passed, one at each end of the stomach, so as to do away with this irregularity of outline. Special care was taken to round off the pyloric end so that no bulging or kinking would be possible. Previously to the introduction of the sutures I had made a careful examination of the pylorus and duodenum and had satisfied myself that there was no growth or stricture or other abnormal condition there. Such is a brief account of the various surgical procedures which have been suggested and adopted, and, so far as the mere manipulative part is concerned, I think there can be little doubt that the operation I

[2] I have seen this patient to-day (April 12th). He now weighs 9 st. 6 lb. and makes no complaint save one—of temporary loss of appetite. He looks well, eats well, and enjoys his food. There has been no return of the vomiting.

employed has considerable and striking advantages over the others. It is easy to perform, rapid in its execution, and has the advantage, possessed by none of the others, that one can see exactly how much of the wall of the stomach is being included; all the sutures can be passed before any one is tied, and, finally, it brings into apposition the walls of the stomach in a way best calculated to produce firm adhesions. The roll which projects into the cavity of the stomach is much smaller than might be anticipated and has, I should

FIG. 2.

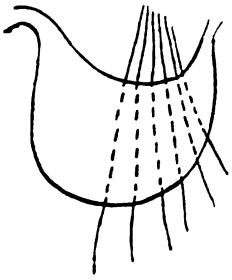

Diagram illustrating the method of introducing stitches.

suppose, none of the possible disadvantages possessed by the long, flaccid, and pendulous folds produced in other operations. The abdominal incision in Bircher's and Brandt's operations was made parallel to the costal margin. In Bennett's case and in mine a medium incision was employed.

Such then, is the operation of gastrorrhaphy or gastroplication. It is a procedure which, so far as one can judge from the scant material at hand, is likely to have a certain range of usefulness when employed in suitable cases. What the ultimate position of the operation in surgery will be it is at this early period quite impossible to say. There are many points upon which we require more precise and more accurate information before a trustworthy and reliable decision can be arrived at. We must learn the frequency of the condition of atonic dilatation, so-called, of cases, that is, of enlargement of the stomach where the symptoms are due, not to any catarrhal or other organic disease in the walls of the viscus, but merely to the bigness of the organ, and where medical treatment has proved of little or no avail. Upon this point the physicians are the most competent to pass an opinion. It will be for them to say when, and in what case, a procedure of this sort is likely to be useful. We must so far as is possible guard against operative interference in cases not wholly suitable. In one case, at least, amongst the few already recorded there was an ulcer with some thickening at the pylorus and no very great distension of the stomach.

In judging of the mortality we cannot place any reliance upon statistics based on so few cases, but it is only reasonable to suppose that as the time occupied by the operation is brief, and as little or no material damage is done to any organ, the risks cannot but be very slight.

As regards permanence of relief there is again very little evidence upon which to base one's judgment. The only case of recurrence of symptoms is that under Mr. Bennett's care already mentioned. What seems most striking on reading the records of these cases is the immediate relief from the severe and most disabling symptoms which is invariably observed; whether such relief is permanent is a question which can only be answered in the future; but I think we may fairly argue that the more permanent the adhesions we produce by the operation we select the more likely are we to secure prolonged or possibly complete and lasting relief. The operation is as yet only in a tentative stage and it is solely for the purpose of calling attention to it as a procedure with some arguments to recommend and facts to justify and support it that I have ventured to introduce the subject.

DRAINAGE OF TAUNTON.—At a special meeting of the Taunton Town Council held recently it was decided to adapt the present Taunton sewage works to the septic tank system and to apply for sanction for a loan of £18,250 for carrying out these works.

ACUTE ATROPHY OF THE LIVER.

BY WILLIAM O'NEILL, M.D. ABERD., M.R.C.P. LOND.,
LATE PHYSICIAN TO THE LINCOLN GENERAL DISPENSARY AND TO THE LINCOLN LUNATIC ASYLUM, ETC.

WITH kind permission I would mention in THE LANCET a case of acute atrophy of the liver, or, as the disease is sometimes called, fatal or malignant jaundice, which came under my care some little time ago.

On Nov. 16th, 1897, I was requested to see a respectable married man, aged forty-six years. He was tall and slender and up to this illness he had not required medical advice since he consulted me sixteen years previously for some slight ailment. He was abstemious and correct in his mode of living and fortunate in having little or no anxiety on his own account or on that of his family. His house, which was rather small, was pleasantly situated and the drainage of the premises was very good. I found that the patient was slightly jaundiced and in a state bordering on collapse. He complained of headache, nausea, and vomiting, but more especially of an intense pain in the hepatic region. I ascertained that the temperature was below normal and that the pulse was small and weak and about sixty beats in the minute. The tongue was furred, the bowels were confined and the urine was scanty and contained some bile. There was no distension of the abdomen and he only felt tenderness when I pressed my fingers under the right ribs. The illness began on the 13th with chilliness and headache, followed by sickness of the stomach, pain in the right side, some yellowness of the skin, and rapid loss of strength. On the 12th the patient had spent the greater part of the day in laying down oilcloth on his kitchen floor and his wife thought that he had caught cold in so doing owing to the frequent opening of the back door, which admitted currents of cold air. The patient was ordered a stimulant and anodyne draught in effervescence, hot fomentations to the painful part, and injections of warm water, which brought away dark-coloured evacuations. The next morning I found that the pain and sickness of the stomach had subsided and the patient expressed himself as feeling so well and comfortable that a speedy restoration to health was confidently anticipated by himself and family and it was proposed that on the following Sunday thanks should be offered up in church in gratitude for the quick relief he had obtained from his great sufferings. His mind was quite clear, but his manner was more excitable than usual and the yellow colour of the skin had increased a little in intensity. The temperature was normal and the pulse was good and about 70 to the minute. On examining the abdomen I discovered that the liver was much smaller and the spleen was considerably larger than in health. A dose of a purgative saline mixture with ammonia was directed to be given every three hours, but few doses of it were taken. In the course of the evening the patient began to wander in his mind and to be drowsy. The delirium and drowsiness increased during the night and on the following morning he was lapsing into deep coma. The coma becoming profound he passed quietly away without having been convulsed in the slightest degree. Two hours before the patient's death the temperature had risen to 104° F. and the pulse was very quick and irregular.

The interesting points in this case were the short duration of the disease, which barely exceeded five days, and the great intensity of the pain in the hepatic region, which so resembled the pain caused by the passing of gall-stones that on my first seeing the patient I thought this might be the case. The following morning, however, although he felt better and appeared to be so to his family, I began to suspect the possibility of the development of a more serious state of things than I had apprehended the evening before and my suspicions were strengthened when I discovered that the liver was shrunken and that the spleen was larger than normal. When the symptoms of coma set in there could be no longer any doubt about the nature of the disease and the result to be expected.

It is evident that acute atrophy of the liver is a general disease in which all the organs of the body suffer more or less as well as the liver and in all probability micro-organisms of a malignant character are the exciting cause of the malady. In the above case the wind coming in through the back-door or the effluvium arising from the oilcloth may have been carriers of the microbes, which could

easily enter the body through the medium of the lungs. But whatever the noxious poison was, the effects, especially toward the end, resembled, to my mind, those of opium poisoning with the exception that opium contracts the pupils of the eyes whereas in this case the pupils were widely dilated.

Shrinking of the liver in connexion with fatal jaundice was noticed as far back as 1826 by Dr. Allison of Edinburgh and a few years afterwards by Dr. Bright of London, and subsequently to this the same pathological appearance was observed by Dr. Graves of Dublin. In 1840 an interesting account of three cases of this disease was sent by Dr. Hanlon of Portarlington, Ireland, to Dr. Graves. The three patients were sisters, the oldest of whom was seventeen years of age and the youngest eight years of age. The two elder patients died comatose and the youngest recovered, a very unusual occurrence in this disease. In 1845 Mr. Busk and Dr. George Budd examined microscopically a liver that was taken from a man who died from fatal jaundice in the Seamen's Hospital and the appearances they noticed were much the same as those described by modern observers. But shrinking of the liver is not a necessary or constant pathological appearance in fatal jaundice. In 1891 a case came under my observation in which the liver was much larger than normal. The patient was a stout woman, aged forty years, who had suffered a long time from disease of the heart of an obstructive character. The abnormal size of the liver was caused, I think, by the diseased heart, and it may be that the congested state of the liver prevented its shrinking, which it might have done if the disease of the heart had not existed. The woman, who had an enlarged spleen, died comatose about a week after the jaundice set in. Neither of the foregoing patients presented any indication of hæmorrhage, but I remember a case of fatal jaundice in which it was a formidable complication. The patient was a fat, fair-haired woman of about forty-six years of age, who after a severe wetting and prolonged exposure to cold was seized with pain in the right side, followed by vomiting and other severe symptoms and jaundice. To relieve the pain leeches were applied and when they had fallen off the bleeding continued and could not be effectually stopped; then followed hæmorrhage from the bowels and stomach and patches of ecchymosis appeared on the skin and also an innumerable number of small spots of blood extravasation resembling fleabites. Soon after the bleeding set in the woman lapsed into coma, in which state she died after an illness that did not exceed ten days.

Fatal jaundice is one of the rarest diseases in this country with which the physician has to contend, and happily for his peace of mind that this is so, for in his encounter with it he hardly ever comes off victorious. It may therefore be conjectured that the treatment of the malady is most disappointing. Treatment can relieve pain and suffering it is true, and this in itself is a great boon to the sufferer, but it is, I think, nearly futile in arresting that downward course which ends in Sheol. Saline purgatives, quinine, mineral acids, and astringents when bleeding takes place have been recommended. But from the nature of the disease what we want is some ingredient which would grapple with, and render innocuous, the microbes or other noxious matters circulating in the blood.

Lincoln.

THREE UNUSUAL CASES OF RENAL CALCULUS.[1]

BY WILLIAM HENRY BATTLE, F.R.C.S. ENG.,
ASSISTANT SURGEON TO ST. THOMAS'S HOSPITAL AND SURGEON TO THE ROYAL FREE HOSPITAL.

I HAVE thought that a short account of some unusual cases of renal calculus would be of interest to the Fellows of the Medical Society of London and have selected three from amongst those which have been under my care during the past year or so. The surgeon is so frequently called upon at the present time to perform the operation of nephro-lithotomy that the account of an ordinary case is no longer of interest excepting to the surgeon himself and the patient who is relieved of the stone. The cases which I have selected are as follows: (1) a case in which constant hæmaturia, although the patient was lying in bed, had persisted for some time unaccompanied by pain of a nature to permit of our diagnosing the site of the calculus; (2) one in which some pain in the kidney had persisted for ten years without renal colic but in which the symptoms made diagnosis easy; in this case the stone was of unusual formation; and (3) a case of acute pyonephrosis due to obstruction of the ureter, in which nephrotomy was required and a stone removed, subsequent exploration of the ureter performed, and later a pultaceous mass expelled per urethram after which the lumbar wound closed.

CASE 1.—A woman, aged forty-four years, was admitted to the Royal Free Hospital under the care of Dr. Calvert on Jan. 4th, 1894. Five years before she had undergone abdominal section for the removal of uterine appendages, but otherwise, with the exception of symptoms of cardiac trouble, she had had nothing noteworthy in the way of illness. Six weeks before admission she had had a more severe attack of pain in the region of the heart than ever before and a month ago she had noticed blood in the urine. It was dark in colour and there was a little pain after micturition. This had continued unchanged until admission. On admission she had pain and tenderness over the cardiac area with evidences of hypertrophy of the heart and disease of the mitral valves. The urine was of a dark red colour and was acid with a specific gravity of 1014; it contained blood but no pus cells, casts or crystals. The patient said that there was some pain on both sides of the spine in the lumbar region and she complained of tenderness on pressure over both kidneys, but the kidneys could not be felt nor was there any difference in the amount of resistance on the two sides. I saw the patient for the first time with Dr. Calvert on March 1st. There had been little change in the state of the urine since her admission to the hospital although she had been kept in bed all the time. The urine had been acid and uniformly of a dark red tint. Many examinations had been made and although the quantity of blood corpuscles found did not quite account for the amount of colouration of the urine there was no doubt of their presence and in addition a varying amount of pus had been observed from time to time. Examinations for tubercle bacilli had yielded a negative result. She admitted that during some months she had suffered on and off from backache, but affirmed that this had not been more marked on one side of the spine than on the other. I recommended operation, but the patient did not agree to it, and a trial of hammamelis was made but without appreciable effect on the bleeding until the dose had become about a drachm three times daily, when the urine cleared somewhat. During the next few days she had a good deal of backache and stated that the pain invariably began if she turned on her left side and started in the right side, being relieved if she turned on the right side or on her back. Before she gave consent to the operation, which was performed on July 7th, there had been but little improvement in the condition of the urine, although for a time the amount of blood passed appeared to almost disappear under the use of the hammamelis. The state of the heart was better, the pulse becoming more regular and less rapid, whilst there was less complaint of pain. Ether was administered and the operation was well borne. An incision was made through the old scar in the middle line and the kidneys were explored. The right one was larger than the left and contained a hard substance in its pelvis. The abdominal wound was therefore temporarily closed, the patient turned on the left side and a stone removed from the right kidney through the loin in the usual manner. The substance of the kidney on its posterior aspect close to the pelvis was incised and the finger was inserted. The stone, which was very irregular, with one branch running at right angles to the main part and posteriorly, was extracted with some difficulty as the forceps frequently slipped in consequence of the crumbling of a layer which covered the surface. Altogether it measured about 2½ in. in circumference and was composed of a hard dark mass covered with a softer, greyish, friable layer of phosphates. The main portion was oxalate of lime. The upper part of the kidney pelvis was dilated, but no change in the lining of the pelvis was apparent to account for the bleeding. The wounds were then closed, a drainage-tube being inserted into the lumbar one. The left kidney was apparently normal. The weight of the calculus was 116½ grains.

Recovery was slow although there was nothing noteworthy as to the manner in which the wounds closed. At the end of a fortnight there were no blood corpuscles to

[1] A paper read before the Medical Society of London on April 25th, 1898.

be found on microscopical examination of the urine but pus cells could still be found. During the early part of August she passed small fragments of calculus per urethram; this was probably the result of the crumbling of the phosphatic envelope of the main calculus when it was taken away at the operation, for considerable difficulty was experienced in clearing away the smaller pieces from the renal pelvis. The state of her heart necessitated her remaining in the hospital until the end of the year, and whilst under treatment she frequently complained of backache and pain across the loins, but it is very probable that much of this was neurotic, for as her health improved so the pain diminished. It was not easy to account for the hæmaturia in this case, for the amount of blood in the urine was considerable, it had persisted for some time, and it continued although the patient was kept strictly in bed. We agreed that the diagnosis was between calculus of the kidney and new growth. In favour of the former was the history of lumbar pain with on more than one occasion a paroxysmal attack, although nothing like renal colic was described. The absence of renal enlargement was in favour of this, and later the presence of an uncertain though always small amount of pus in the urine. It was not, however, possible to guess as to which kidney was affected, there being an almost complete absence of localising signs. I spoke to the patient about the pains in her back when she was convalescing from the operation and said: "But you never had pain in the right side more than in the left," to which she replied: "Oh, yes, I had." I asked: "When?" and the answer she made was: "Why, the night before the operation."

The only case of stone in the kidney with such excessive hæmaturia which has been under my personal observation was one associated with a villous tumour of the renal pelvis and I ventured to diagnose tumour in addition to calculus on account of the excessive hæmorrhage. It was hardly possible to exclude villous growth of the pelvis of the kidney without exploration, but the absence of the other signs of new growth made it evident that no malignant growth was present in this case.

CASE 2.—A woman, aged twenty-one years, was sent to be under my care at St. Thomas's Hospital from Rugby by my friend Mr. Relton and she was admitted on April 10th, 1897. She had been seen by Mr. Relton ten years before for pain in the side and hæmaturia. He had diagnosed a renal calculus and recommended operation, but her parents had refused. She had never had severe pain nor did it at any time resemble renal colic and she had been able to do her work regularly, but the pain was fairly constant and of a dull, aching character, worse on exertion and when she was tired. Recently her parents had been alarmed by three or four attacks of hæmaturia of rather more severe character which had compelled her to lay up. When four years old she had had jaundice and had suffered from dysmenorrhœa for the last five years, but otherwise with this exception she has managed to do her work. The family history was good. When admitted to the hospital she was a healthy looking girl of good colour and complained of a dull, aching pain in the right side. Nothing abnormal could be felt in the abdomen. There was no tenderness over the kidney and no rigidity of muscles or undue fulness in the side. The urine was of specific gravity 1020, acid, clear, and pale, with a slight deposit of mucus; there was a very slight amount of albumin but no sugar. Dr. Blacker kindly examined the case in the x ray department with the screen and made the following note: "Fluorescence extremely good; indistinct opacity was seen in the right upper half of the abdomen, marked towards the middle line, but no definite area of opacity was made out. The whole of the right side of the abdomen was darker than the left." When lying still she had no pain, but the visit to the x ray department caused her to complain again of it, but there was no blood in the urine. On the 26th there was still a fair trace of albumin and the urine showed the presence of oxalate of lime and a few uric crystals on microscopical examination. There were also a few pus cells. On May 5th there was no albumin in the urine and on that day I removed a calculus from the kidney through a lumbar incision. This calculus was felt on palpating the kidney to be placed in the upper part. An opening was made through the substance and the finger was passed into the pelvis of the organ. A very rough stone was felt in the upper part which could not be dislodged with forceps until it had been actually dug out of the renal tissue by means of the fore-finger and a director; it was embedded in the tissue of the posterior and upper part of the kidney and its separation was attended and followed by a good deal of bleeding. The kidney was apparently quite normal. Afterwards for the first few days there was a good deal of blood in the urine and the drainage-tube which had been inserted after the operation was removed and the wound was plugged with cyanide gauze for five days. No suppuration followed and the after-course of events was satisfactory excepting for the presence of blood in the urine. This, however, was found for a fortnight only, gradually disappearing. She left for her home on the 30th and has continued well.

The stone which was removed was apparently divided into two parts, the smaller somewhat rounded part, to which torn renal tissue adhered, and the larger, which was almost of the size of a peach-stone and greatly resembled a dry one on the surface, the crystals being large and arranged in laterally opposed plates with sharp edges. It was a pure calcium oxalate stone.

This case is interesting from the peculiar arrangement of the oxalate crystals, which had caused the stone to assume a very uncommon appearance. This has been decribed by Mr. Shattock and Dr. Ord in their paper read before the Pathological Society of London, but is not mentioned in our text-books and is found in very few of our museums. Moreover, surgeons with large operative experience have not met with it. This case is additionally interesting from the peculiar way in which the stone was held up in the kidney, which accounts, I think, for the absence of renal colic. Movement would jar the stone but would not dislodge it and although the history was of unusually long duration and the stone had reached a considerable size there was no evidence of disease of other parts of the kidney. From the difficulty in separating the stone and from the fibrous character of the soft tissue which remained on the part of the stone which had been buried, as well as from the hæmorrhage attending its removal, I am of opinion that it had formed in the renal tissue and not in the pelvis or in a calyx.

I have here another oxalate of lime-stone which I removed from one of the cases on which I operated last Wednesday. It resembled in appearance a miniature hen on a pedestal, the body of the bird being bent down as if pecking at something near its feet. The pedestal part, which is the smaller, was contained in a dilated calyx, whilst the narrow part was tightly nipped by the opening into the renal pelvis. The small calculus accompanying was in a cyst which communicated with the dilated calyx in which part of the larger stone was held. The patient, a young man, had had symptoms for many months but had not had a definite renal colic.

CASE 3.—A girl, aged seventeen years, was admitted under my care into St. Thomas's Hospital on Dec. 15th, 1894, suffering from severe pain in the right side of the abdomen. Two years before she had had an attack of pain in the right side and vomiting, followed by the passage of a small calculus, and she was ill for a week. Some months afterwards she had another similar attack, which passed off in a few days, but no calculus was passed on that occasion. The present illness commenced suddenly three days before admission with severe pain in the right side of the abdomen and vomiting which lasted until admission. There was no history of tubercle in the family, but her father had undergone the operation of nephrectomy for some disease of the kidney the nature of which they did not know. The muscles on the right side of the abdomen were rigid and much tenderness was complained of on palpation. A large swelling was present in the right lumbar region extending from the level of the anterior superior spine of the ilium to the under surface of the liver. There was absolute dulness in the flank, but the exact limits of the swelling could not be well defined on account of the acute tenderness. No fluctuation could be felt. The specific gravity of the urine was 1030; it was scanty, neutral in reaction, with some deposit of urates. The rapid course, large size, acute pain, and tenderness of the swelling and its extension into the iliac fossa made the question as to its origin in the appendix one to be considered, but it was thought most likely to be a pyonephrosis due to obstruction of the ureter by calculus. Hot fomentations were applied and the patient was kept quiet in bed on a liquid diet. Two days after admission the swelling was larger, better defined, and fluctuating. She was irritable but inclined to sleep. The temperature was 102·4°F. There was now no vomiting. In the afternoon the kidney was exposed through a lumbar incision, tapped, and a large quantity of pus was

evacuated. Through the enlarged opening an ovoid uric acid calculus measuring 1 in. by ½ in. was extracted; it was lying loose in the abscess cavity. No other stone could be felt either in the kidney or the ureter and it was considered inadvisable to make any prolonged search, although the opinion was held that the cause of the condition had not been found. This opinion was confirmed by the later progress of the case, for no blood appeared in the urine after operation nor was its amount increased. The patient was much relieved as a result of this incision into the kidney and urine escaped from the wound without any diminution in its quantity until Feb. 5th, 1895. During the earlier part of this time there was an admixture of pus, but later it was almost normal. The quantity of urine passed by urethra varied from 10 oz. to 25 oz. in the twenty-four hours. A drainage-tube had been kept in the loin wound as it was considered best to give the opening in the kidney a chance to heal before the soft parts. As the flow of urine did not diminish and the diagnosis was that a small calculus obstructed the ureter exploration of the ureter was decided on and carried out on Feb. 5th through an incision in the right linea semilunaris. The ureter was traced from the renal pelvis down to the bladder. No stone could be felt and the only thing that appeared unusual was a limited thickening, not well defined, where the ureter crossed the pelvic brim; above this the ureter appeared to be somewhat dilated, below it was apparently normal. The pelvis of the kidney was normal and it was very interesting to find that the kidney itself had resumed its proper size and shape. Examination of the bladder after dilatation of the urethra with the finger yielded a negative result, as also did examination by the rectum. The wound was sutured in layers. Incontinence of urine followed and lasted for five days, but she suffered no further inconvenience from the examinations. As no calculus had been found in the urinary passages and obstruction continued it was decided to try what pressure from above would do and with this object the drainage-tube was removed from the loin wound which was allowed to close. No result was apparent until Feb. 19th, when the patient complained of severe pain on micturition and passed a pulpy mass of greyish colour, of the size of a hazel nut with 11 oz. of urine. In less than three hours' time 18 oz. were passed without pain. The wound in the loin rapidly closed, the quantity of urine passed daily was natural, there was no pus in it, and the patient was able to leave the hospital on Feb. 24th and has continued well since.

The history of old attacks of renal colic made it appear probable that the case was one of blocking of the ureter by a calculus and the formation of an acute pyonephrosis. At all events it appeared probable that the sudden onset of symptoms indicated an obstruction of the ureter from within, and when at the first operation the only stone found was in the abscess cavity and not definitely in the pelvis of the kidney or entrance of the ureter, when the urine from the affected kidney all came through the lumbar wound and it was evident that the obstruction continued, exploration was clearly indicated. The result of this being negative as regards calculus made it probable that the block was caused by some softer substance, but the condition of the ureter as found at the second operation did not help very much in the clearing up of this point. The complete recovery from such a large pyonephrosis is also noteworthy, for the kidney was apparently normal when examined on Feb. 5th through the abdominal incision.

Mansfield-street, W.

ON PRIMARY ENTERECTOMY IN CASES OF INTESTINAL GANGRENE, WITH AN ILLUSTRATIVE CASE.

BY CUTHBERT LOCKYER, M.B., B.S. LOND., F.R.C.S. ENG.,

PATHOLOGIST TO THE SAMARITAN FREE HOSPITAL FOR WOMEN; SURGICAL REGISTRAR TO CHARING-CROSS HOSPITAL AND DEMONSTRATOR OF SURGERY IN THE MEDICAL SCHOOL.

PRIMARY resection as a treatment for gangrenous bowel was for years the subject of controversy among surgeons. Before the use of the various cylinders and plates it was doubtless preferable in many cases to produce an artificial anus with a view to subsequent resection rather than immediate enterectomy, on the ground that owing to the very critical condition of patients suffering from acute obstruction the prolonged and tedious operation for suturing the gut after resection would not be well borne. By the aid of the various mechanical devices of recent invention the slow process of Lembert's stitching is rendered unnecessary and the time taken to complete the anastomosis is reduced to a minimum. It has thus come about that the entire operation of resection and bowel union has been effected in the short space of twelve minutes and the possibility of such a feat has given popularity to the plan of removing gangrenous or suspicious bowel as soon as the latter has been cut down upon. On turning for a moment to the teaching of statistics overwhelming evidence is to be found in favour of primary resection of gangrenous bowel; for instance, Lockwood,[1] after analysing 37 cases of gangrenous hernia treated by artificial anus at St. Bartholomew's Hospital, finds that this method yields a mortality of 89·18 per cent. Again, Mikulicz[2] showed that in 168 cases which were collected from the practice of seven operators and in which the two operations—resection and the formation of an artificial anus—were included the mortality after resection amounted to 47·1 per cent., whilst that after the formation of an artificial anus amounted to 76·6 per cent., and Mikulicz himself performed 21 resections with 14 recoveries, and of the 7 deaths only 2 were attributable to the method employed, whilst in 7 cases in which he made an artificial anus all ended fatally. Zeidler's[3] figures throw light upon the treatment of gangrenous hernia; 289 cases of resection show a mortality of just over 49 per cent., whilst 287 cases of formation of an artificial anus show a mortality of over 74 per cent. — i.e., 25 per cent. greater. Glass[4] in 1897 collected 48 cases of resection with 3 deaths, or 6·25 per cent. McCosh[5] tabulates 115 cases of resection, of which 50 per cent. were fatal, and Razoumowski of St. Petersburg collected 26 cases of primary resection for strangulated hernia with 7 deaths only—12·26 per cent. It will be seen, therefore, from the above statistics that primary resection of sphacelating gut gives the patient the best chance of recovery in the majority of cases. I do not mean to imply by this that the older operation is to be entirely abandoned; that cannot be, for in cases of diffuse peritonitis or in cases of profound collapse resection would be out of the question and the establishment of an artificial anus the only justifiable surgical procedure. Likewise in cases of marked meteorism and distension all that can be done is to make a temporary opening in the distended gut.

Having assigned to primary enterectomy its proper place in surgery the question which next presents itself is—What method shall be employed in the intestinal anastomosis? Having regard to methods in vogue a threefold choice is open to the operator: (1) simple suturing; (2) suturing with the aid of temporary splints; and (3) the use of metal buttons. The method of suture with a temporary splint is the oldest, for French surgeons employed the trachea of a calf for this purpose in the thirteenth century. Next in point of antiquity is the simple suture which was first successfully performed by Ramdohr in 1780. The metal bobbin was first heard of in 1847, when Deman[6] employed a combination of three rings and a spring in bowel union; this is the prototype of the Murphy button. I may say at once that each plan has its supporters. There are surgeons who advocate the use of unaided suture to the exclusion of all mechanical assistance; on the other hand, there are surgeons who invariably give the sutured bowel the support to be derived from a button or a bobbin. The latter class of operators differ only in their opinion as to the relative advantages of the metal buttons as compared with the bobbins made of decalcified bone. With regard to simple suturing several plans have been devised. First come the Lembert and Czerny-Lembert stitches. To the use of these for end-to-end anastomosis there are objections. Both Jacobson and Treves are agreed that from twenty-five to forty-five stitches are required, and these will take considerable time to adjust. Moreover, for approximation by suture one requires good healthy peritoneum to work upon, and this cannot always be obtained, especially in cases where adhesions exist, for here peritoneum

as such may have disappeared in newly formed tissue or after separation become too attenuated to support the sutures; therefore it is clear that there are cases where simple suture cannot be carried out. Many surgeons argue also that it is not always possible to effect a watertight union by the Lembert stitch. Maunsell's method of suturing has promised much, especially in intussusception, but it is open to the serious objection that the stitches pass through all the coats of the bowel and leakage of intestinal contents may follow its use, as was shown to have occurred in three cases recorded by Bidwell from the practice of the West London Hospital; and, further, the line of union has been known to yield, giving rise to septic peritonitis. Mayo Robson says the peritoneum is more likely to be infected by this than by any other method of suture. A method of suture not generally practised, but which strongly appeals to me, is that devised by Leonard Rogers.[7] He acts on Greig Smith's statement that a sero-fibrous is the firmest union, and accordingly strips a collar of serous membrane from one of the cut ends of the gut, thus baring its muscular elements; he then sews the serous coat of the other end to the muscular coat of the end prepared, draws the peritoneal collar over the first row of stitches and sews the edge of the collar to the serous coat of the other end of bowel. There are therefore two rows of stitches, one through serous and muscular (now buried) and one uniting serous to serous. The serous coat strips easily and the operation takes half an hour. This plan acted well in the case of dogs experimented upon by Rogers, but has not yet to my knowledge been tried on the human subject. The time taken up in suturing will, I think, militate against its becoming the favourite method of union, but it has very strong supporters in Harrison Cripps, Bruce Clarke, and Abbé, the latter surgeon having discarded his catgut rings in favour of plain suturing. In comparing the statistics of the suture with those of approximation by mechanical means I find that in Mayo Robson's[8] 26 cases the mortality for unaided suture was 55·3 per cent., whereas the mortality in cases where his bone bobbin was used was only 8·3 per cent. Weir was able to collect 35 cases of primary suture in which all the patients died. It is only fair to mention that Edmunds and Ballance,[9] as the result of operations on the thicker intestines of dogs, came to the conclusion that simple suturing is the best plan both for lateral and for end-to-end anastomosis. For the former they advise Halstead's and for the latter Maunsell's method. The salient objection to simple unaided stitching is that it takes up so much more time than union by a button, and since it must be granted that it cannot be suitably adapted to meet all cases I will take in review the various mechanical appliances at the command of the surgeon. Some are digestible but others are not. Of the former I may mention Neuber's, Mayo Robson's, Allingham's, Ball's, and Bailey's decalcified bone bobbins, also Senn's plate and Paul's invagination tubes, Abbé's catgut bobbin and Beasley's catgut and rubber ring. Then come the non-digestible supports, such as Murphy's button, with modifications by Jackson Clarke and also by Miller, Frank's coupler, Chaput's bobbin of malleable tin, A. J. Downe's (Philadelphia) rubber collapsable bags, and further suggestions have been offered by Cheatle, Hastigan, and Frank.

To make a comparison between the relative merits of the several appliances would occupy more space than is placed at my disposal. I will content myself by saying that were it not for the fact that Murphy's metal button has such a brilliant record of successes to show I would leave the metal bobbin out of consideration altogether. The great plea for the use of any appliance is that by so doing the operation is shortened in point of time and better union is likely to be got when the bowel is kept at rest by a temporary splint. Since Murphy's button has been so far the most popular instrument its merits and demerits are worthy of discussion. Its merits rest on results. Murphy[10] records 27 cases in which the button was used with 9 deaths, and 5 only of these were from preventable causes. In Robson's hands the button had a mortality of 20 per cent. In 1896 Banks records its use in 7 cases with 2 deaths. Kummell[11] collected 17 cases of resection in 15 of which Murphy's button was used; 3 deaths occurred soon after operation, and of the remaining 12 all lived for some considerable time and 6 are recorded as having completely recovered. Carle[12] has used the button fifty times with good results and he also records that during the last two years he and his assistant Fantino have used the button twenty times for gastro-enterostomy with no death. In Graff's collection of 25 cases for 1893 to 1895 the button was in no case the cause of death. Individual successes are far too numerous to mention. Despite such a run of good fortune very serious objections present themselves in the use of the button. Amongst the many drawbacks may be mentioned (1) stenosis of the gut as a sequel; (2) obstruction of the small lumen; (3) failure to pass (4) gangrene extending from the seat of pressure or set up by the button in its passage down the canal; (5) injury to the bowel during closure by the pressure of the fingers causing the sharply cut apertures for drainage to lacerate the mucous membrane; (6) impossibility of disarticulating the button once it is closed; and (7) erosion of the spring by gastric juices. Chaput[13] cites 3 cases of stenosis and Ball[14] records a case, but this is not peculiar to Murphy's method; in my opinion it is far more frequent after simple suture. Chaput mentions 4 cases of obstruction and he does not agree with Meyer and Murphy, who say that purgation will overcome this difficulty. As to delay in passing there are many cases on record where the button has not passed at all. Murphy mentions 4 cases, Meyer 2, and Morton 1. In Allas's[15] case the button was retained for 16 months and in Wyeth's[16] case for 127 days. In Quenin's case it was retained till death 16 months later. Kammerer attempted extirpation after the button had been retained for 12 weeks and the patient died from peritonitis. The ileo-cæcal valve is the point of hindrance to the passage of the button, for in the case of double resection recorded by Glass the button he inserted into the large intestine passed on the fifth day, whilst the one which united the ends of the small gut took 28 days in its passage. The long delay of the button in the bowel is a very serious drawback. Its presence, as will be seen in the case published below, gives rise to sharp attacks of colicky pains and localised tenderness; but, what is worse, it may give rise to a series of ulcers along the alimentary tract and some of these may perforate. Again, gangrene and perforation have occurred 20 times to Chaput's knowledge. Quite recently this accident happened in a case at Charing-cross Hospital under the care of Mr. Morgan, and most surgeons are acquainted with this serious objection. I believe the objection raised to the use of the button in operations on the stomach is entirely theoretical, for there is very little hydrochloric acid present in cases of gastroectasis, especially if the stricture is malignant, and it would be a very simple matter to gild the button if necessary. These manifold objections have resulted in modifications of the button being devised by Jackson Clarke, Miller, and others, and new methods of anastomosis are still being suggested by Cheatle, Frank, and Hastigan. In point of dispatch Murphy's plan of anastomosis is *facile princeps* and its introduction is a matter of extreme simplicity, and for these reasons it will always have a place in intestinal surgery. The main risks in its use lie in its slow passage endangering the entirety of the bowel and the liability to gangrene of the bowel around the button whilst it remains *in situ*. I predict, therefore, that the decalcified bone bobbins will ultimately prove to be of greatest service in aiding intestinal anastomosis.

A woman, aged seventy-seven years, was admitted into Charing-cross Hospital under the care of Mr. Bloxam on Aug. 16th, 1897. She was suffering from strangulated femoral hernia. Two months before admission to hospital she fell down a flight of twelve steps and afterwards noticed a swelling in the right groin. Four days before admission to hospital acute symptoms set in and became aggravated up to the time of admission. The patient was operated upon at once. When the sac was opened a quantity of thick, grumous, fœtid fluid escaped and a knuckle of small intestine about 4 in. in length was exposed. The loop was intensely congested and at its convexity there was a gangrenous patch of the size of a florin. The vessels of the

corresponding portion of the mesentery were congested but were not thrombosed. Having regard to the patient's great age the establishment of an artificial anus was suggested, but the anæsthetist (Mr. Bellamy Gardner) agreeing that the operation could proceed a portion of the gut 4½ in. in length was removed, the stricture having been eased by a vertical cut directly upwards through Poupart's ligament. A Murphy's button with a diameter of 1⅛ in. was inserted in the usual way and all bleeding points in the mesentery were secured. The parts were cleansed with a 1 in 2000 perchloride solution and the bowel together with the mesentery was returned into the abdominal cavity through the enlarged crural opening. The sac was ligatured and cut off, the deep parts were united with a fishing gut stitch, a drainage tube was inserted between the skin and the muscular planes and the superficial wound was sewn with interrupted fishing gut sutures. The pulse was 104, regular, and stronger after the operation than it had been before it. In the after treatment nothing was given by the mouth except sips of warm water for four days; small nutrient enemata were administered every two hours and all were retained. The patient passed a large stool from the lower bowel during the night after the operation. Two days after the operation flatulence became troublesome and great relief was obtained from turpentine enemata. The drainage-tube was retained for two days. The superficial wound suppurated for a while owing to contamination by the fluid in the hernial sac at the time of the operation. Hypostatic congestion set in at the bases of the lungs ten days after the operation. The patient suffered from colicky pains and some localised tenderness in the right iliac fossa which was worse at some times than others and these were complained of until the button was passed on the thirtieth day after operation. She left the hospital five weeks after the operation. I visited the patient at her home on Jan. 19th, 1898, and found that the wound was sound, that there was no sign of hernia on coughing, that the bowels were acting quite regularly and without pain, and that beyond the fact that she was seventy-eight years of age she had nothing to complain of.

I believe that the pain and tenderness in the right iliac fossa noted in the above case were caused by the button's passage being obstructed by the ileo-cæcal valve. That the button might be in the rectum was put out of court by examination for it in that situation. With regard to the division of Poupart's ligament, as Ball has pointed out, this does not weaken the abdominal wall any more than an incision in any other part of the abdomen. In the above case the soundness of the wound at the present time bears out this statement. Resection through the original wound presents less risk of infection than the plan practised by some surgeons of opening the abdomen and drawing the gangrenous bowel from the crural canal across the peritoneal cavity and resecting through a second wound. The great age of the patient is the most remarkable feature in the case. I am indebted to Mr. Bloxam for permission to publish the case and also to Mr. Morgan for permission to mention a recent case of his by way of illustrating a point in this paper.

Charing-cross Hospital.

LLANELLY HOSPITAL.—Owing to the resignations of the nursing staff at the Llanelly Hospital the committee of that institution has decided to temporarily close the hospital except in cases of serious accidents.

THE NEUROLOGICAL SOCIETY OF LONDON.—This society held its first meeting out of London on April 23rd, when, at the invitation of Dr. Alexander Hill, vice-Chancellor of the University, a meeting was held in the Physiological Laboratory at Cambridge. The following communications were made:—Dr. Alexander Hill: Some Specimens of Granules (demonstration).—Professor MacAlister: The Race-characters of Australian Brains (demonstration).—Dr. J. N. Langley: Some Points relating to the Sympathetic System (demonstration).—Dr. Gaskell (for Miss Alcock): The Distribution of the Facial Nerve in Ammocœtes.—Dr. F. E. Batten: (1) Nerve Terminations in Muscle Spindles (demonstration); and (2) (for Dr. Sihler of Ohio), Motor Nerve Termination within the Muscle Spindle (demonstration).—Dr. Mott: Degeneration of the Neuron (demonstration). At the conclusion of the meeting members and visitors were entertained at dinner by the Vice-Chancellor in Downing Hall.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON FOUR CASES OF PUERPERAL ECLAMPSIA.

BY G. FOWLER, L.R.C.P. EDIN.

CASE 1.—The patient was a married woman, aged eighteen years, eight months pregnant with her first child. There was no neurotic family history. The patient enjoyed perfect health till the day before I was sent for. She then complained of giddiness and flashes before her eyes and voided a very small quantity of urine which coagulated into a semi-solid muddy-looking mass. When I arrived at the house in the morning she had passed a restless night and complained very much of "slight twitches" (spasmodic contractions) of her hands and feet. I gave her full doses of chloral and applied mustard sinapisms to her calves. Two hours after I was hastily summoned as she had had a general convulsion and was quite unconscious. I found her in a violent general epileptiform seizure, having bitten her tongue rather severely. I tried to prevent her from further damaging her tongue by means of a gag and at once administered chloroform and kept her under its influence for nearly half an hour. As long as she was under the anæsthetic no convulsion existed, but as soon as its effects had passed away the fits came on again at regular intervals. As a last resource, considering the gravity of the case, with the consent of those most interested in her, I induced premature labour, dilating the os by means of Hegar's dilators and Barnes's bags, and when the os had fully dilated ruptured the membranes and delivered her with Simpson's long forceps. The whole operation lasted some time but was to my entire satisfaction. The child was stillborn. After delivery the mother had one severe convulsive seizure and from this time all proceeded well, the patient gradually recovering consciousness but having no recollection of what had occurred for some hours previous to or during labour. Since then I have delivered this patient of her second child, a healthy male, which presented in an occipito-posterior position.

CASE 2.—The patient was a married woman, aged twenty-one years, seven months pregnant with her first child. I was hurriedly summoned to see her as she had had a number of fits and was quite unconscious. When I arrived I found that both the upper and the lower extremities were very much swollen and œdematous. Urine had not been voided for twenty-four hours. Digital examination revealed an almost fully dilated os, a roomy pelvis, a cranial presentation, and the membranes intact. Fearing the onset of further convulsions I at once ruptured the membranes and awaited the result. This increased the uterine contractions, but unhappily while the head was rapidly descending a severe convulsive attack came on resembling an epileptic fit and this seemed to stop the further progress of the labour. This convulsion was soon followed by another, the fits occurring at regular intervals. As the head appeared to me to be acting as an irritant by its pressure, and being also well within reach, I resolved upon instrumental delivery and delivered the patient without any difficulty of a living male child. The placenta followed rapidly. The patient had no more fits, passed urine eight hours after the birth of the child, and progressed favourably, the urine remaining albuminous for about three days. Both child and mother are now doing well.

CASE 3.—This patient resembled Case 1 in every respect. I treated her in the same manner and was successful in delivering her of a living child. Both mother and child progressed favourably.

CASE 4.—The patient, a rather anæmic young woman with a good previous history, was taken in a fit four days after the birth of her first child, which was born without the aid of a medical man. The temperature was normal and the lochia were healthy. The urine was albuminous. There was no rupture of the perineum. The fits occurred at regular intervals and the patient remained in a semi-comatose state between them. I gave her full doses of chloral by the

rectum and administered chloroform and injected pilocarpine hypodermically. This treatment benefited the patient, especially the administration of chloroform, which kept the seizures well under control. She had no convulsive seizures for about a couple of hours after the administration of chloroform had been stopped. I then left her to see another urgent case and returned just in time to see the patient in a violent general convulsion in which she died (probably asphyxiated).

Certain points are worthy of note in these cases: (1) the disregard the majority of patients pay to the premonitory symptoms, sending for medical aid only when the eclamptic seizures come on; (2) the value of instrumental delivery and the induction of premature labour in certain cases of puerperal eclampsia; (3) the value of chloroform in controlling the fits; (4) the appearance of albumin in the urine of all four patients and its complete disappearance three or four days after delivery in the first three cases; and (5) the fact that all four patients were primiparæ.

A CASE OF SPASMODIC DYSPNŒA.

By J. E. S. BARNETT, F.R.C.S. ENG.

THE patient in the present instance was a male child who soon after birth began to suffer from attacks described by his mother as "grunting and blue all over." When he was three and a half months old I saw him and learned that the fits were becoming more frequent and enduring. His breathing was laboured, with suprasternal and subcostal recession during respiration, locomotion of the larynx, and action of the nares. During an attack these symptoms were intensified and in addition cyanosis became marked in the lips, face, and finger-nails. In the intervals there was free but noisy entrance of air into both lungs. The temperature was 97·8° F. in the groin, the heart sounds were normal, and the apex was in the natural position. The child was unusually fat and big for his age and he took his mother's breast well. The fits became more severe, threatening dissolution, and the mother was anxious that something should be done. Treatment by hot fomentations and by a steam-kettle under a tent proved useless. Papilloma and spasmodic catarrhal laryngitis were thought of as possible conditions. Tracheotomy was performed on March 17th, 1898, the infant being then four months old. No difficulty was experienced except in the introduction of the tube; the smallest vulcanite was used. There was no marked immediate relief, but next day the breathing was less laboured, and although the fits persisted the cyanosis was lessened and for the next day or two was absent. No œdema, emphysema, or suppuration occurred about the wound and the child's condition improved; his temperature remained normal throughout except for a rise to 100° on one evening. When the vulcanite tube was removed it was replaced first by a Parker's and afterwards by a Morrant Baker's rubber tube. Three weeks after the tracheotomy the child suffered from a prolonged attack of dyspnœa, became gradually more and more cyanosed, and eventually died. At the post-mortem examination it was found that the thymus gland was enlarged and that outlying lobules of gland tissue extended well into the root of the neck. Perhaps the recurrent laryngeal nerves were irritated and set up spasm of the larynx which the tracheotomy relieved, but the gland still growing caused direct and fatal pressure on the trachea. From the appearance of the parts when the deep fascia was divided this pressure must have been considerable. There was neither ulceration of the trachea nor papilloma of the larynx.

Paddington.

A CASE OF SHINGLES OCCURRING PRINCIPALLY ON THE SCAR OF A BURN.

By HERBERT FREDERICK, L.R.C.P. LOND., M.R.C.S. ENG.,
LATE ASSISTANT HOUSE SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE patient in this case was a boy, nine years of age, who came under my care on Dec. 6th, 1897, for well-developed shingles on the left side of the trunk. On Nov. 22nd, 1893, he had an extensive burn on the left thoracic and abdominal regions, owing to his nightshirt catching fire. He was treated as an in-patient at St. Mary's Hospital for eigh weeks. When I first saw the patient I was informed that twelve hours previously—i.e., about 9 P.M. on the previous evening—he had suffered from great pain in his left side which was so severe as to make him scream and to keep him awake during the early part of the night. On examination I found that he was a well-nourished boy with an extensive scar on his left chest, side, and abdomen. The skin was puckered and reddish in colour, with bands of thick fibrous tissue running in all directions. He was suffering from typical shingles on the left side. The rash started from the tips of the eleventh and twelfth dorsal and the first lumbar vertebræ and was continued round the left side in a band varying in breadth from 1½ in. to 3½ in. The greater part of the rash was on the site of the scar, though several groups of vesicles were present on the otherwise healthy skin. Two or three spots were on the right side of the middle line both in front and on the back. The rash presented nothing atypical; it was confluent in places and pain of a neuralgic character was present with considerable intensity. The child seemed to be poorly and his appetite was bad. His mother told me that he had been "out of sorts" for the last few days. During the nights of Dec. 6th, 7th, and 8th he could only sleep lying on the left side—the side of the lesion. The treatment consisted in protecting the side with absorbent wool and in giving tincture of perchloride of iron internally; 3 grains of calomel were given on the nights of the 6th and 7th, followed for a week afterwards by 3-grain powders of mercury with chalk at bedtime. The disease ran the usual course and recovery took place without any unusual symptoms. The neuralgic pain disappeared completely on the 10th.

The interest of the case seems to lie in the following points. It is not often that one comes across a case of shingles occurring on the site of such an extensive burn. Personally I have never seen one before, nor have any of my medical friends to whom I have detailed the case. From the nature of the scar it is evident that the skin over the burnt area must have been pretty thoroughly destroyed down to the deeper layers of the dermis and consequently the nerve terminations must have been destroyed too. The few spots occurring on the right side of the median line both on the back and front demonstrate very prettily the overlapping of the nerve-supply in those regions. This point is noted by Fagge,[1] but the case negatives his assertion that "pain of a neuralgic character is entirely absent in young patients." The mother put the child to bed herself and is certain that no spots were present—in fact, until the morning she thought the pain was due to pleurisy.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.

A CASE OF TRAUMATIC TETANUS TREATED BY ANTITOXIN ON THE SEVENTH DAY AFTER INJURY; DEATH.

(Under the care of Dr. CURNOW.)

ON several recent occasions we have published in "The Mirror of Hospital Practice" reports of cases of tetanus in which the antitoxin has been employed and we gladly print the following cases as it is advisable that as many of these cases as possible should be put on record, for the value of tetanus antitoxin is still debateable. We would not suggest that the antitoxin has no controlling power over the disease for its efficacy in this respect has been abundantly established, but it cannot be said that at present we are in any degree certain of the frequency with which the antitoxin should be given or even of the most suitable dose for any given case. Cases of tetanus vary

[1] Fagge and Pye-Smith: Text-book of the Principles and Practice of Medicine, third edition, vol. ii., p. 939.

greatly in severity and recovery follows even without antitoxin in no very small proportion of cases. The mortality has varied in statistics from 83 to 93 per cent., but as these statistics chiefly refer to pre-antiseptic days it is not improbable that the rate of mortality in recent years would be much less. It is the opinion of many that the treatment with the tetanus antitoxin has not materially modified the death-rate. So far as our knowledge goes at present the most important factor in the prognosis is the length of time which has elapsed from the infliction of the wound to the development of symptoms. The later the spasms appear the better the prognosis. It may also be said that if the patient survives the tenth day of the illness he will probably recover. Kneass [1] says that the mortality in 61 cases which he had collected and which had been treated by antitoxin was only slightly less than that under other treatment, but Marson [2] collected 38 cases treated with antitoxin and of these 25 recovered. For the notes of the case we are indebted to Mr. A. E. Griffin, house physician.

The patient, a seaman, aged fifty-two years, was admitted to hospital on Feb. 14th, 1898. He had been out of work for some months and had been doing odd jobs about the docks. On Feb. 7th, seven days previously to admission, he cut his right thumb when chopping some wood. On the 11th he had some pains in the neck which he attributed to rheumatism. On the 13th he complained of pains in the back and on the 14th on rising he noticed that his neck was retracted and that he was unable to depress his jaw. He was able to swallow at breakfast-time, but later in the day he could not swallow at all. On admission at 4 P.M. his temperature was 98·6° F. and his pulse was 84 and regular. The respiration was normal. His head was thrown back and there was a compensatory curve in the spine. There was complete inability to swallow; he had spasm of the masseters with frequent grinding of the teeth. The muscles of the arms, legs, and trunk were not affected. The patient had walked to the hospital. Both knee-jerks were increased; the plantar reflexes were also increased, but no ankle clonus was present. On the palmar surface of the right thumb there was a superficial abrasion 1 in. in length grimed with dirt, but there was no inflammation or tenderness round the wound. Tetanus antitoxin having been sent for from the British Institute of Preventive Medicine, 10 c.c. were injected into the subcutaneous abdominal tissues at 9 P.M. on the day of admission and at the same time an attempt was made to pass the stomach-tube through a gap in the teeth, but the spasm of the pharynx was so great that the attempt was abandoned, and a simple enema having been administered nutrient enemata were given every four hours. The patient slept from 11 P.M. till 12 P.M. and it was noticed that he sweated profusely. His temperature was then 97·6° and his pulse was 84, strong and full. He had a slight spasm at 2.30 A.M. on the 15th and a somewhat more severe one at 4.30 A.M. When seen the spasm was over and he was lying quite quiet, his pulse being 108. 10 c.c. of antitoxin were injected at 5 A.M. When seen again at 10 A.M. he was sweating profusely; he complained of pain across the chest; the muscles of the neck were firmly contracted; there were occasional spasm of the masseters, with grinding of the teeth, and slight spasm of the back muscles with accompanying rigidity of the chest wall and slight dyspnœa during the spasms, which came on at intervals of about a quarter of an hour. The arms and legs were not affected; he could roll himself over and preferred to lie on the left side. His pulse was regular, 96, and the temperature was 98·2°. He had retained the nutrient enemata. The urine was highly coloured, acid, and of specific gravity 1020; there was a deposit of urates, but there was no albumin. At 2.40 P.M. a third injection of 10 c.c. of antitoxin was given and he was seen about this time by Dr. Curnow. At 4 P.M. the patient was much in the same condition but there was more inclination to spasm of the chest wall, synchronous with the spasm of the head and face muscles. There was no risus sardonicus; during the spasms there was slight rigidity of the arms and abdomen. At 5 P.M. the spasms became more frequent but not more severe. At 5.45 P.M. the patient had a violent spasm but no opisthotonos; after the spasm, which lasted three minutes, the patient's muscles became flaccid, then respiration and pulse gradually failed and he died at 6.5 P.M., the respirations apparently ceasing first. No post-mortem examination was performed.

Remarks by Mr. A. E. GRIFFIN.—Dr. Curnow has kindly given me permission to report the case. It is a matter of regret that I did not push the antitoxin to a greater extent. The patient died while I was in town getting a further supply, but the fact that seven days had elapsed before the patient sought relief greatly militated against a successful result. We were unable to obtain a post-mortem examination, but the wound was excised with the surrounding tissue. Dr. Newman, of the King's College Bacteriological Laboratory, kindly examined the excised portion and has demonstrated the presence of Nicolaier's bacillus. The case is of interest in that there was neither opisthotonos nor risus sardonicus, the pulse was never small and quick, and the temperature was subnormal.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY.

THREE CASES OF TETANUS.

(Under the care of Mr. T. P. GREENWOOD.)

FOR the notes of these cases we are indebted to Mr. Stanley Copley, house surgeon.

CASE 1.—A man, aged thirty-four years, was admitted into the infirmary on Dec. 15th, 1897. He had suffered from an ulcer on the right leg for some years. He first noticed that his neck and jaw were stiff on Dec. 11th. When he was admitted he had well-marked risus sardonicus. The jaw was nearly closed and there was marked and continuous opisthotonos and the abdomen was rigid. Both legs were a little stiff; the rest of the body was unaffected. There was a very foul ulcer of a chronic character on the inner side of the right leg. The temperature was 97·4° F., the pulse was 80, and the respirations were 24. He had some spasms, affecting chiefly the back and limbs; there were about six spasms an hour. He was admitted at 1 P.M. and at 2.45 P.M. 3 grammes of Tizzoni's antitoxin were injected. At 3 P.M. A.C.E. mixture was administered, the ulcer was scraped to the bones and its edges were excised freely. The whole raw surface was then cauterised with fuming nitric acid. In the next three hours he had eight spasms. At 6 P.M. another 1½ grammes of Tizzoni's antitoxin were injected. He passed a bad night with very little sleep, being awakened by severe spasms, about ten occurring every hour. During the 16th his condition remained much the same, the spasms averaging ten an hour. He took food well. A gramme of Tizzoni's antitoxin was injected at 9.30 A.M., another gramme was injected at 1 P.M., and 1½ grammes were again injected at 6.30 P.M. He had no sleep until midnight; then 15 grains each of chloral hydrate and bromide of potassium were given and he obtained two hours' sleep. He had on an average seven spasms per hour during the night and on the next day (the 17th) he seemed to be holding his own. The bowels acted freely after an aperient pill. The pulse was rather slower (65). A gramme of antitoxin was administered at 10 A.M. and another gramme at 4 P.M. The bromide and chloral draught was repeated at night and it seemed to have a good effect in reducing the number of the spasms and produced two and a half hour's sleep. On the 18th the left leg was noticed to be stiff, the opisthotonos was more marked, and the jaw was more fixed. A gramme of antitoxin was given at 10 P.M. and between 10 A.M. and 4 P.M. the spasms were reduced to five an hour. From 4 to 10 P.M. the spasms increased in severity and in number (averaging eleven per hour), so 1 gramme of antitoxin was injected at 9 P.M. and at 10 P.M. 20 grains each of bromide and chloral were given. It was noticed that the right inguinal glands were enlarged and tender. The patient passed a bad night, having only one and a half hour's sleep; he had many severe spasms, these averaging eleven an hour. On the 19th the spasms were very frequent and severe. Both legs were rigid and marked opisthotonos was present. The jaw was quite closed. The ulcer was dressed. The slough was separating. The right inguinal glands were enlarged and tender and he declared the spasms started from these glands. At 10 A.M. 10 c.c. of antitoxin from the British Institute of Preventive Medicine were injected. The spasms continued to be severe and frequent; 20 grains each of bromide and chloral were given at midday with no effect and were repeated at 4 P.M. with 20 c.c. of antitoxin (British Institute of Preventive

Medicine). At 6 30 P.M. the patient was in great pain with severe and frequently repeated spasms. He had had sixty-nine spasms since midday. The draught of bromide and choral was repeated at 8 P.M. At 11 P.M. the severity of the spasms was still continuing. A temporary improvement was noticed between 8 and 9 P.M., there being only eleven spasms per hour, but he had twenty-six spasms between 9 and 11 P.M. At 11 P.M. the patient was crying out with pain. A hypodermic injection of morphia (¼ grain) was given and A.C.E. mixture was administered until the spasms relaxed. The breathing was a little laboured at first under the anæsthetic, but as the anæsthesia deepened it became quiet and he remained so for an hour. The spasms then gradually returned and became very severe between 2 and 3 A.M. (the 20th). Bromide and chloral (of each 20 grains) were given at 4 A.M. and were repeated at 8 A.M. The bowels acted freely between 9 and 10 A.M. after a minim of croton oil had been administered in the form of a pill. From 7 to 10 A.M. great improvement in spasms was noticed, there being on an average only four an hour. After 10 A.M. on the 20th he seemed to be better; the spasms were less frequent, being 3 or 4 per hour. Antitoxin (British Institute of Preventive Medicine, 20 c.c.) was given at 4 P.M. and 10 c.c. at 11 P.M. The administration of bromide and chloral (20 grains of each) was continued every four hours. He slept for short intervals during the day. An erythematous rash appeared on the upper part of the thighs. He passed a restless night, sleeping for two hours only, and the spasms averaging seven or eight per hour. On the 21st the rash was well marked; it consisted of irritable red blotches over the upper part of both thighs, the lower part of the abdomen and the upper part of the arms. Slight icterus was visible. Antitoxin (30 c.c.) was given at 10 A.M. and the bromide and chloral were continued every four hours. The temperature, the pulse, and the respirations kept about normal. The wound on the leg, which since the operation had been dressed with iodoform, was thoroughly washed with formalin solution (1 per cent.) and a compress of the same solution was applied. This was done, as the case gave the impression of its being one in which fresh toxins appeared to be formed from day to day, and it was concluded that all the tetanus bacilli in the wound had probably not been destroyed. Another 20 c.c. of antitoxin were given at 6 30 P.M. He passed a much better night, the spasms being less frequent and less severe. The chloral and bromide were omitted after 3 30 P.M. On the 22nd antitoxin (20 c.c.) was injected at 10 A.M. The patient expressed himself as feeling much easier and the rash was fading. 10 c.c. of antitoxin were given at 2 P.M. Altogether he had a much better day, but he again passed a restless night. The bromide and chloral were given every four hours during the night. On the 23rd antitoxin (20 c.c.) was administered at 7 A.M. The masseters appeared to be relaxing and allowed the little finger to pass between the teeth. The formalin dressing on the leg was reapplied. By 6 P.M. there was decided relaxation of the spasm all over the body and the index finger could be introduced between the teeth. The bromide and chloral were again omitted after 8 A.M. On the 24th the improvement was maintained, the spasms averaging during the day only three per hour; 10 c.c. of antitoxin were given at 10 A.M. He passed the best night since his admission. On the 25th 10 c.c. of antitoxin were given at 10 A.M. He was certainly improving and he had only two spasms per hour during the day. The dressing on the leg was changed to dry gauze dressing. From this date he steadily improved with gradual diminishing stiffness and spasms up to the 30th, when the spasms ceased entirely though some rigidity remained in the legs, the jaw, the abdomen, and the back, rigidity in the last preventing his sitting up. On Jan. 8th, 1898, he was so far recovered as to sit up and walk about, but some rigidity remained in the right leg and in the back. He was discharged on Feb. 1st. The ulcer was healing and looked healthy. There was still some slight stiffness about the back and the right leg. This remained up to the middle of March. No antitoxin was used after 10 A.M. on Dec. 25th, 1897. He had altogether 13½ grammes of Tizzoni's antitoxin and 180 c.c. of antitoxin from the British Institute of Preventive Medicine. His largest dose of antitoxin in one day was 50 c.c. on Dec. 21st, corresponding to the turning-point of his illness. It was thought that this large dose of 50 c.c. enabled his natural forces to gain the upper hand and in another similar case as much would be given at the first dose. The antitoxins did not appear to be as beneficial in controlling the paroxysmal spasms as chloral and bromide. Great relief to these spasms was also obtained by free purgation with croton oil. From the probable source of infection being a chronic ulcer of the leg it was not possible to calculate the incubation period. It will be noted also that the formalin dressing was also applied on the day of most improvement and this may have contributed to the subsequent recovery.

CASE 2.—A man, aged sixty-seven years, crushed his left hand between the wheel of a cart and a wall while he was carting manure on Feb. 23rd, 1898. The hand and wound were very dirty and the wound suppurated subsequently. He first noticed stiffness in his neck on March 1st and he was unable to swallow on the following day. He was admitted into the infirmary at 7 P.M. on the 2nd and it was noticed that the wound on the back of his hand, part of which was held together by two silver sutures, was suppurating and sloughing and that there was a fracture of the fourth metacarpal bone communicating with the wound. The risus sardonicus was marked and the muscles of the neck were stiff. The tongue could just be protruded between the teeth. Opisthotonos was present and the abdomen was very rigid. He was unable to speak clearly and he was quite unable to swallow anything. A.C.E. mixture was administered at 9 P.M. and the wound was cleansed, its edges and sloughs were excised and with them the whole of the fourth digit and its metacarpal bone. The wound was thoroughly swabbed with formalin solution (1 per cent.). The patient passed a bad night, having practically no sleep, and as he was quite unable to swallow anything 30 grains each of chloral and bromide were given per rectum at 11 P.M. On the 3rd he was very rigid and stiff and he was quite unable to swallow even the mucus in his throat, which nearly choked him at times. The pulse was 132. There were no spasms or rigidity of the limbs. He was fed every four hours with nutrient enemata and suppositories. He gradually became more and more cyanosed and he died at 1.30 P.M. Unfortunately no antitoxin could be procured in time for this case. It was severe in all its aspects.

CASE 3.—This case did not occur in the infirmary, but it has been thought well to give it in connexion with the two other cases of tetanus. A woman, aged forty-seven years, was first seen on Feb. 16th, 1898, when she complained of pain in the neck and head. Her temperature was 103° F. The case was thought to be one of influenza, but on the next day, the 17th, she had an anxious expression and slight trismus. A foul varicose ulcer was the only possible site for infection from tetanus which could be discovered. On the 18th chloroform was given and the ulcer was excised freely and its surface was cauterised with strong nitric acid. On the 19th the trismus was more marked and 20 c.c. of antitoxin from the British Institute of Preventive Medicine were injected in the morning and another 20 c.c. in the evening. On the 20th the spasms were frequent and painful; the trismus was rather less. A hypodermic injection of morphia (⅓ gr.) was given at night and 20 c.c. of antitoxin were injected in the morning and repeated again in the evening. On the 21st she seemed to be easier and the spasms were less severe; 20 c.c. of antitoxin were given in the morning. The patient died rather suddenly with symptoms of cardiac failure at 8 P.M. No post-mortem examination was allowed. It was thought that the patient was improving under the antitoxin and that the cause of death was cardiac failure of which the origin was not quite clear.

EXETER DISPENSARY.—The annual report of the Exeter Dispensary which has just been issued shows that 6338 patients had been treated during 1897, an increase of 67 on the previous year. Since the institution was founded in 1818 there have been 270,000 patients attended. The financial statement showed that there was an adverse balance of £50.

METEOROLOGY AT SOUTHPORT.—The report of the Corporation Meteorological Observatory for 1897 is a record of most careful and minute work on the part of Mr. Baxendell, the borough meteorologist, and his staff of assistants. The report contains an account of the varying instruments used and a number of very full tables of results. The publication of results of observations such as these on the meteorology of health resorts and watering-places in general must be of great interest as bearing upon certain departments of public health.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Albumosuria in which the Albumose was spontaneously precipitated.

A MEETING of this society was held on April 26th, the President, Mr. BRYANT, being in the chair.

Dr. T. R. BRADSHAW (Liverpool) read a paper on a case of Albumosuria in which the Albumose was spontaneously precipitated. The patient was a man, aged seventy years. There was no history of any previous illness. For nearly a year he had passed turbid milky urine two or three times a week which deposited a copious white sediment which was amorphous and gave the reactions of a proteid. The clear urine passed at other times contained in solution a proteid which gave reactions of an albumose and appeared to be the same body as was precipitated in the turbid specimens. It coagulated at a temperature of from 50° to 60° C. and was partially dissolved again on boiling. Coagulation took place at a lower temperature when the urine was made more acid. Coagulation took place with nitric acid and the coagulum dissolved on heating and came back on cooling. Coagulation was also brought about by hydrochloric acid and sulphuric acid. A detailed description was given of the characters of the urine. Dr. Bradshaw thought that spontaneous precipitation depended on variation in the quantity of the other constituents of the urine. Five cases reported by previous observers, in which a substance resembling that here described was found in the urine, were quoted. The present case was apparently unique in respect that the albumose was precipitated in the urinary passages. In several recorded cases the condition had been associated with disease of bones and bone marrow. Dr. Bradshaw's patient also showed kyphosis and immobility of the lower vertebræ, but the exact character of the disease in the bone was not yet evident.

The PRESIDENT thanked Dr. Bradshaw for his interesting communication. He was particularly interested in the surgical questions raised and from the appearance of the photographs he could not help wondering whether the case could possibly be one of osteitis deformans.

Dr. SIDNEY MARTIN said that some years ago he had had the opportunity of investigating a similar case in which there was spontaneous precipitation of albumose. The patient was a woman who was under the care of Dr. H. R. Spencer for an ordinary multilocular ovarian tumour which was removed. Soon after she began to pass albumose, the urine being milky, and at first it was supposed to be a case of chyluria. No bone disease was detected, but there was hypertrophy of the left ventricle and other signs of chronic renal disease. He agreed that there should be a distinction between these cases and those in which a small quantity of albumose appeared in the course of fevers. He was not inclined to lay very much stress on the exact form of albumose present, as the different albumoses — hetero-, proto-, and deutero- — formed a progressive series between albumin and peptone. The substance met with in the urine in cases like Dr. Bradshaw's was usually spoken of as hetero-albumose, but it differed from true peptic hetero-albumose in not being dialysable. It differed from deutero-albumose in being redissolved after coagulation in a 0·2 per cent solution of caustic soda. Further observations were necessary to show whether the body more closely resembled proto-albumose or the forms more allied to peptones. It had been supposed by some that the substances were formed by the action of pepsin in the urine on albumin, but there was hardly time for such a change to take place. In the cases associated with multiple new growth the rapid degeneration of the cells led to the formation of proteids which could not be used within the body and were excreted. A similar albumose to that found in the urine in these cases could be obtained by boiling splenic extract with caustic potash.

Dr. H. D. ROLLESTON asked whether the blood serum had been examined. Fifteen months ago Chataigne had described cases in which the blood serum was lactescent, the condition being specially associated with parenchymatous degeneration of the renal epithelium and met with also in cases of chylous ascites. With regard to the association with bone disease he mentioned a case of multiple myelomata recently reported in the *Journal of Pathology* by Dr. Parkes Weber. In that case there were homogeneous patches seen in microscopic sections of various organs which were possibly albumose precipitated by the hardening reagents.

Dr. LEE DICKINSON had met with both proto- and deutero-albumose in the urine of patients suffering from pneumonia, in some cases as much as 1 per cent. The cases were always marked by severe symptoms, depression, low tension pulse, and hæmorrhagic tendency, similar to what was observed on injection of mixed albumoses into the blood of animals. Virchow and others had shown the presence of albumose in the marrow in cases of fragilitas ossium. Thus this substance must traverse the body before being excreted by the kidney.

Dr. BRADSHAW, in reply, said that after careful examination of the patient no sign of osteitis deformans could be detected. It had been suggested that the spinal changes might be due to senile caries and a case of senile caries had been mentioned to him in which there was milky urine. But there was no necropsy in that case and it was possibly not caries. It had only been recognised of late years that many of the cases of fragilitas ossium were really cases of multiple sarcoma of bones, and he thought that it was probable that the case under the care of Sir Thomas Watson which had become classical through the investigation of the urine by Dr. Bence Jones was of this nature, and it was to this category that he would provisionally refer his own case.

MEDICAL SOCIETY OF LONDON.

Some unusual Cases of Renal Calculus.—Central Galvanisation in Cardiac and other Neuroses.

A MEETING of this society was held on April 26th, Dr. HOLMAN, Vice-President, being in the chair.

Mr. W. H. BATTLE read a paper on Some Unusual Cases of Renal Calculus, which will be found on page 1180 of this issue of THE LANCET.—Dr. HOLMAN recalled the days when there was intense antagonism to abdominal surgery and referred to the rapid strides which renal surgery had made. He detailed one case in which renal calculus had occurred in a patient who also had myxœdema. She rapidly responded to thyroid treatment, but pain began in the right kidney, and this had been preceded for some years by hæmaturia and pus in the urine. In July, 1897, as these attacks were more frequent and acute, and there were symptoms of blocking of the ureter followed by pyonephrosis, the kidney was incised and a large quantity of pus was evacuated, but no stone was found. Recently, however, he had been able to pass a probe down the ureter and could feel a stone, which he hoped might be extracted later.—Mr. BRUCE CLARKE referred to the necessity of passing some instrument down the ureter at the time of the operation. In several cases he had succeeded in finding a stone by this means, employing for the purpose a black rubber bougie, which could often be passed down as far as the brim of the pelvis. He thought that the excessive hæmaturia was due partly to the character of the stone and partly to its position.—Mr. MARMADUKE SHEILD asked what was Mr. Battle's experience as to the value of the x rays in determining the presence of a calculus. The chief difficulty in diagnosis was in the discrimination from renal tuberculosis. He asked whether Mr. Battle had ever employed the inoculation test. In one case under his care some of the urine from a doubtful case had been injected by a pathologist into the peritoneal cavity of a rabbit and gave rise to typical tuberculosis.—Mr. BATTLE, in reply, said that in one of his cases he had attempted to probe the ureter during the operation, but owing to the disturbance of parts he could not find the opening of the ureter. Hæmaturia was very variable. It was greater in the case quoted, in which there was a smooth phosphatic coating, than in the case where there was a spiny surface. No doubt this was due to closer attachment of the latter. His experience with the x rays led him to believe that, though occasionally successful, skiagraphy could not be relied on. He had no personal experience of the method of making inoculations for diagnostic purposes.

Mr. WILLIAM ARMSTRONG (Buxton) read a paper on the Therapeutic Value of Central Galvanisation in Cardiac and other Neuroses. He drew attention to four factors which had tended to discredit the use of galvanism to the higher nerve centres: (1) want of precision in application and failure to estimate the exact dosage administered; (2) use as a last

resort in hopeless cases; (3) extravagant claims made for it; and (4) the blatant quackery which has so often been associated with it. He contended that it had only a limited field of usefulness, like any other remedy, but that within those limits its effects were definite and fairly certain. The physiological effects were threefold—stimulating, sedative, and tonic. The stimulating effect was immediate, the sedative quickly followed, and the tonic came on more slowly. The most important effect was upon nutrition. During the passage of the current through the body heat was generated, substances were transferred from one pole to the other, endosmosis and exosmosis were modified, and there was a marked acceleration of the process of oxidation. Secretion was largely influenced, as was excretion, especially in those gouty cases where there was deficient excretion of urea and uric acid. The structures mainly influenced by this method were the medulla, the pneumogastric nerves, and the sympathetic system. The various methods of application were discussed, preference being given to the "Rockwell," in which the kathode was applied to some indifferent part to avoid vertigo and nausea. The necessary appliances were described and stress was laid upon the need for a good galvanometer and rheostat. The strength of the current and the duration of the sittings were detailed. The applications should neither be too long nor too strong and attention was drawn to the following symptons which showed need for special care: headache, insomnia, nausea, over-excited pulse, and prolonged reaction of the nerves of special sense. Cases presenting the following symptoms were considered as suitable for treatment, but stress was laid upon the necessity for elimination in the first instance of all reflex sources of irritation, especially in cases of cardiac neuroses, migraine, and spasmodic asthma: (1) cardiac and gastric neurosis; (2) neurasthenia and hypochondriasis; (3) cerebral exhaustion; (4) migraine; (5) exophthalmic goitre; (6) Raynaud's disease; and (7) spasmodic asthma. The therapeutic effects noted were a feeling of better health, an increase in brightness and clearness of thought, an improvement in appetite and digestion, and a marked decrease in the formation of indican, skatol, cresol, and oxalates. Sleep was markedly increased and was more calm and peaceful. The action of the heart became more regular, anginoid pains were relieved, the rapid pulse became slower, and the unstable nerve centres were steadied so that they were not so readily acted upon by reflex causes, such as flatulence, absorption of toxins, &c. Neurasthenia benefited largely, the vicious circle formed by the instability of the nerve centres and the abnormal products of deranged digestion being broken through. Details were given showing excellent results achieved in cases of cardiac neuroses, neurasthenia, cerebral exhaustion, exophthalmic goitre, migraine, Raynaud's disease, spasmodic asthma, "dry tongue," and diabetes insipidus.—Dr. G. HEBSCHELL said that he had used central galvanisation for ten years and could confirm what had been said as to its beneficial results. It was particularly valuable in relieving that class of neurasthenic patients in whom there was auto-intoxication. In such cases he, in addition, washed out both the stomach and the lower bowel. In applying the current he did not send it through the brain, but applied the positive pole to the nape of the neck and the negative pole to the epigastrium for ten minutes. He afterwards removed the electrode from the nape of the neck and placed it over the sympathetic ganglia in the front of the neck. He avoided the use of a dual collector on his battery, as the sudden changes in the strength of current produced by it caused vertigo He used a special graphite rheostat made by the Chloride of Silver Dry Cell Company of Baltimore. Patience was required, as much good was rarely seen until after from ten to fifteen sittings, but, on the other hand, treatment was rarely necessary for more than five weeks. He had seen galvanisation arrest the paroxysms of spasmodic asthma.—Dr. LEWIS JONES said that the value of general galvanisation had been rather lost sight of for some years. It was of the greatest value in the treatment of various disorders of nutrition and the effects could be particularly well seen in rickets, chilblains, and Raynaud's disease. He preferred to apply it in the form of an electric bath, using sinusoidal currents from the main. He had never seen any permanent benefit from its use in exophthalmic goitre.—Dr. ABRAHAM observed that central galvanisation and electric baths were very different things. He thought that central galvanisation had been largely abandoned in favour of D'Arsonval's method of currents of high intensity. He asked what was supposed to be the advantage of stimulating the cilio-spinal centre in connexion with cardiac neuroses.—Dr. HEDLEY confirmed the value of the treatment. He remarked that the high frequency currents which had been referred to were still on their trial, but he himself expected great things from them.—Mr. ARMSTRONG, in reply, expressed his great pleasure that Dr. Herschell, Dr. Lewis Jones, and Dr. Hedley concurred in the general principles he had laid down, although their modes of application differed somewhat from the one he had used. His experience confirmed that of Dr. Lewis Jones concerning the use and the value of the sinusoidal bath in rickets and chilblains. Dr. Abraham, in accusing them of using methods as diametrically opposed as a Turkish bath and a cold bath, must surely have forgotten that there was such a thing as reflex impression conveyed from the peripheral nerves and from the spinal sympathetic ganglia to the brain. Dr. Lewis Jones with his electric bath used the former method and Dr. Herschell the latter. With regard to the smallness of dosage in central galvanisation compared with that of the D'Arsonval current it must not be forgotten that in the former the whole current passed through the centres. In the latter probably but a small portion reached them and that indirectly. The suggestion that the best continental methods were neglected in England was disproved by the fact that he himself was largely using the sinusoidal current mentioned, but while he had found it most valuable in many cases it was much inferior to the central treatment in the class of case under discussion. The alleged uselessness of galvanisation of the cilio-spinal centre was at least open to argument, but he considered that as excitation of this point was so conducted to the cervical sympathetic as to cause dilatation of the pupil it at any rate seemed to point to a method of influencing that important part of the nervous system, and several competent observers have reported definite therapeutic effects following application to that centre only.

CLINICAL SOCIETY OF LONDON.

Renal Calculus.—Thrombosis of the Superior Mesenteric Vein.—Tuberculous Peritonitis with Thrombosis of the Mesenteric Vein.—Raynaud's Gangrene after Parturition.

A MEETING of this society was held on April 22nd, the President, Mr. LANGTON, being in the chair.

Dr. FREDERICK TAYLOR and Mr. ALFRED D. FRIPP related a case in which a Renal Calculus was detected by the Roentgen rays and successfully removed. The patient was a male, aged twenty-six years. He was admitted into Guy's Hospital on Sept. 8th, 1897, under Dr. Taylor. There was a history of mild attacks of colic for nine years, and the symptoms and signs while in hospital pointed clearly to the diagnosis of a right renal calculus, but Mr. Fripp was unable on Oct. 18th to detect it in the kidney through the usual lumbar incision. A week later, guided by a skiagram, he was able, by reopening the wound and removing part of the twelfth rib, to reach and remove the stone from its abnormally high position. It weighed exactly half an ounce and was of the size and shape of the distal segment of a small thumb. It was surrounded by a cyst consisting partly of the pelvis of the kidney and partly of atrophied kidney substance. This was removed as well. The patient made an uninterrupted recovery and has since resumed the active life from which he had been debarred for nine years by the colic. The points of interest in this case were (1) the indication given by a skiagram of the position of a renal calculus that had previously escaped detection by the lumbar exploratory operation; (2) the abnormally high position of the stone—above the twelfth rib, though on the right side; (3) the fact that the twelfth rib had its deep surface covered to a large extent by pleura, even on the right side; and (4) the completely atrophied condition of the kidney.—The PRESIDENT said that the symptoms appeared to be classical except for the absence of hæmaturia. Although he himself had never been able to detect a renal calculus by skiagraphy he had in one instance obtained a definite shadow from a calculus in the upper part of the ureter.—Mr. MAKINS said that there appeared to be great difficulties in obtaining successful skiagrams. Even so skilful an operator as Dr. Barry Blacker had failed repeatedly and in one case in which there were 16 calculi in a kidney no indication of them was revealed on the plate. Although, therefore, positive results were most valuable it

would be long before the existence of renal calculus could be excluded by this method.—Dr. BARRY BLACKER said that he had examined many dozens of supposed cases of renal calculus by this method, but had only been able to suggest the presence of a calculus in three.

Dr. BRADFORD read an account of a case of Thrombosis of the Superior Mesenteric Vein causing Intestinal Obstruction. A man, aged twenty years, was admitted into University College Hospital on Aug. 26th, 1897, complaining of pain in the abdomen and slight diarrhœa. Illness began on Aug. 20th with vomiting and abdominal pain and the diarrhœa did not appear until Aug. 23rd. On admission the diarrhœa had ceased, but there was considerable pain referred to the umbilicus and there was repeated vomiting of coagulated milk. The bowels were opened by an enema and the stools contained no blood or mucus. The abdomen was resonant all over and nothing abnormal was detected on examination. The respiration was rapid and jerky, the pulse was 96, the temperature was 101° F., and the lips were covered with sordes. The patient remained in much the same condition until Sept. 1st, when the abdominal pain became more severe and the vomiting became more frequent. The bowels were opened by an enema. On Sept. 2nd the vomited matter became distinctly stercoraceous and an indefinite mass could be felt in the left iliac region. A few fæcal masses were passed as a result of enemata but flatus was passed freely. On Sept. 3rd the abdomen was opened in the middle line by Mr. Pollard and a distended coil of small intestine was drawn out of the wound; this was purple in colour and greatly swollen and thickened. There was no volvulus and no constricting band was found. The wound was rapidly closed and the patient succumbed shortly after the operation. On post-mortem examination no band or other cause of strangulation was found. The mesentery was thickened and the veins in it were thrombosed; a portion of the jejunum some 18 in. long was greatly swollen and thickened. The superior mesenteric artery and all its branches were normal. The splenic vein was normal. The trunk of the superior mesenteric vein was greatly thickened and the lumen of the main vessel was filled with reddish puriform material. The upper part of the vein was blocked by firm decolourised clot. The disease of this vein extended into the main tributaries of this vessel, but most of the terminal branches had their walls of a normal thickness and appearance, and some of these were free from clot, although the trunk into which they opened was thrombosed. The upper part of the portal vein was healthy. The mesenteric glands were enlarged and congested and one of them lying on the lowest branch of the vein was enlarged and suppurating, and the abscess cavity communicated with the interior of one of the thrombosed veins.—Dr. FREDERICK TAYLOR said that some years ago he had brought before the Pathological Society a case somewhat similar to that described by Dr. Bradford except that in his case it was the artery and not the vein which was thrombosed.—Dr. LUCAS BENHAM asked what medical treatment was adopted and whether hiccough was a prominent symptom.—Dr. TOOGOOD had had a case under his care at Lewisham Infirmary exactly like that described by Dr. Bradford. The symptoms simulated intestinal obstruction, but on opening the abdomen the state of things was made clear. In that case there was not only blood in the peritoneal cavity but also in the mesentery. —Mr. MAKINS had once been called in to operate on a case which proved to be one of thrombosis of the superior mesenteric artery. In this case the onset of symptoms was sudden and not slow as in Dr. Bradford's venous case. The question had been raised whether thrombosis of the artery would lead to gangrene owing to the very free anastomosis of its branches. He reminded the society that last year Mr. Lockwood had read an account of a case[1] in which gangrene occurred from a stab which severed a branch half an inch from the bowel. Probably, however, the anatomical conditions in that case were exceptional. —Mr. FRIPP asked whether it was likely that inflammation had spread from the pancreas to the vein, which passed close by it. Recently there had been a little epidemic of acute pancreatitis, judging from the number of cases brought to Guy's Hospital. In several of them the symptoms during life were those of intestinal obstruction.—Dr. ALFRED HILLIER asked whether the condition of the veins might not have been secondary to some condition of the intestine.—Dr. BRADFORD, in reply, said that the treatment had been palliative only, as the nature of the illness was not recognised.

Mr. RAYMOND JOHNSON reported a case of Tuberculous Peritonitis in which symptoms of Intestinal Obstruction resulted, probably from Thrombosis of certain Tributaries of the Superior Mesenteric Vein. The patient, a woman, aged thirty-three years, who had been ailing for a month, was attacked with sudden abdominal pain four days before her admission to University College Hospital. Vomiting occurred repeatedly, and the bowels failed to act in spite of aperient medicines. On admission the patient presented in a marked degree the abdominal aspect; the tongue was dry and the pulse was rapid; the abdomen was slightly distended and uniformly slightly tender; there was impaired resonance in the left flank, but no tumour could be detected and the pelvic viscera appeared to be normal. The diagnosis of intestinal obstruction was made, but no evidence was forthcoming to indicate its exact nature. On opening the abdomen several ounces of clear fluid escaped and yellow tubercles were seen to be scattered sparsely over the intestines. No kinking or twisting of the bowel could be detected, but a solid mass was felt, which proved to be a fan-shaped portion of the mesentery much thickened and deeply congested. The corresponding eight inches of the intestine was much more congested and swollen than the rest and the tuberculous nodules more abundant over it than elsewhere. The whole length of the small intestine having been examined without finding any further cause for the symptoms the abdomen was closed. The patient was at first fed entirely by the rectum, but after a slight action of the bowels on the day following the operation liquid food was given in small quantities by the mouth without any return of the sickness. At the end of three weeks the patient was able to leave the hospital. The explanation was offered that the condition of the mesentery and bowel resulted from thrombosis of some of the branches of the mesenteric vein caused by the deposit of tubercle around them and that the symptoms of intestinal obstruction resulted from a temporary paralysis of that part of the intestine the circulation of which was interfered with. The case was reported as possibly affording an explanation of the occurrence of acute symptoms during the course of tuberculous peritonitis independently of the ordinary conditions occasioning intestinal obstruction.

Dr. LEE DICKINSON and Dr. W. A. HUBERT read a paper on a case of Raynaud's Gangrene in connexion with Parturition. The case was that of a woman, aged forty-two years, in whom Raynaud's disease set in severely on the second day after parturition but who had had slight attacks during her pregnancy. The fingers and toes were the parts chiefly affected and almost the whole of the ungual phalanges of both hands became gangrenous. There was intense pain in the affected parts. No ergot had been taken. The attack came on without any general or local exposure to cold and was evidently determined by the final strain of parturition after a pregnancy which had been attended by circumstances of privation and ill-health. The patient was suffering from chronic nephritis with hæmaturia and was very anæmic. A second case in which Raynaud's gangrene followed parturition was briefly described and reference was made to two others, one described by Raynaud and the other by Begg in THE LANCET, Sept. 17th, 1870. In the four cases, although ergot was given, it was in small quantities. The influence of conditions of debility, such as that from malaria, anæmia, and hardship, was referred to — Dr. LUCAS BENHAM asked if there were any septic condition following the confinement in either of the cases referred to.—Dr. DICKINSON, in reply, said that there was no history of any septic trouble and very little ergot had been taken.

[1] See THE LANCET, May 22nd, 1897.

HARVEIAN SOCIETY OF LONDON.

The Treatment of Epilepsy in Epileptic Colonies.—Oöphorectomy for Inoperable Cancer of the Breast.

A MEETING of this society was held on April 14th, Dr. JAMES F. GOODHART, the President, being in the chair.

Dr. ALDREN TURNER read a short paper upon the Treatment of Epilepsy in Epileptic Colonies. He referred to the success which had followed the establishment of these institutions in Germany and pointed to the development of this system in America and in England. The epileptic colony at Chalfont St. Peter, Bucks, to which attention was

especially drawn, was founded for the purpose of giving employment to those epileptics, both male and female, who, by reason of their disease, were unable to obtain work or who were discharged from remunerative posts on account of epilepsy. The experience of the colony during the four years of its existence pointed to the fact that the younger the epileptic and the sooner he is admitted after the onset of the seizures the more satisfactory is the result of the general management and *régime* adopted. The principles which direct the management are simple: (*a*) removal of the epileptic from the town to the country; (*b*) regular employment under direction; (*c*) the maintenance of a well-ordered and regular mode of life, with avoidance of excitement and abstinence from alcoholic liquors; and (*d*) abundance of good nourishment of a simple nature. The general result is that the fits in the majority of cases diminish both in number and severity, in some cases to quite an extraordinary extent; the physical health materially improves, while the mental condition in all but a few cases shows obvious improvement.—The PRESIDENT alluded to the beneficial effects which followed admission of epileptics to ordinary hospitals. Some were sent in as suffering from Jacksonian epilepsy and as being in urgent need of operation; but the fits would cease or subside in frequency and severity so long as the patient remained in hospital, although medicines were almost entirely withheld. He mentioned the difficulty of treating epilepsy occurring in those past middle life and instanced the case of a man who after being a great sportsman all his life had become epileptic. He would often be seized by a fit whilst out shooting and would lie down until the attack passed off and then resume his sport. He (Dr. Goodhart) had taken the responsibility of allowing the patient to continue his favourite pursuits in spite of the obvious danger entailed, thinking that the danger to general health would be still greater were the patient to forego the mode of life to which he was accustomed.—Dr. LEONARD GUTHRIE asked whether any provision was made at Chalfont St. Peter for the treatment of epileptic children. He considered that systematic moral training of these—which they rarely got at home—was of the highest importance to themselves and to the community, and it could best be carried out in such colonies as had been described.—Dr. KNOWSLEY SIBLEY remarked that after hearing the paper it had very forcibly struck him that the improvement, both as to the frequency and strength of the fits noticed in so many patients shortly after admission to the epileptic colony, might be the result of the removal of alcohol. His hospital experience had taught him that a large number of epileptics drank more alcohol than was good for them and in many cases they were easily influenced by comparatively small quantities. Undoubtedly the exciting cause of many of the fits was alcohol. The fact that on admission to the colony all alcohol was withdrawn from the epileptics' daily *régime* suggested a probable explanation of the improvement noticed. Dr. Sibley also spoke on the question of drugs and the doses employed.—Dr. TURNER, in reply, agreed that it was most important to deprive epileptics of alcoholic liquors. The question of receiving children at the colony had already engaged the attention of the governors, but there was difficulty in deciding how long they should be kept and what to do with them afterwards.

Mr. WATSON CHEYNE read a paper on two cases of Oöphorectomy for Inoperable Cancer of the Breast. The first patient, a woman, aged thirty-four years, was admitted to King's College Hospital on Oct. 23rd, 1896. Three years previously a cancerous tumour had been removed from her right breast. A year later some enlarged glands were removed from the right axilla. Three weeks before admission to hospital she felt pain along the old scar and noticed an ulcer in the mid-axillary line. On admission this ulcer was of about the size of a shilling, with considerable induration and redness of the skin around. A large, tender, hard mass adherent to the chest wall occupied almost the whole of the right axilla. There were also numerous enlarged glands in the posterior triangle of the neck, but there was no evidence of internal deposits. It was impossible to attempt complete removal of the disease and so with the patient's consent Mr. Watson Cheyne removed both ovaries and tubes on Oct. 28th, 1896. On March 16th, 1897, about four and a half months after the operation, a great deal of the infiltration had disappeared, the ulcer had shrunk to the size of a threepenny-piece, the mass in the axilla was distinctly smaller, softer, and freely moveable, the glands in the neck were very much fewer, they were only about of the size of split peas then, and the larger ones had entirely disappeared. By June 4th, however, there was again distinct increase in the size of the growth and reappearance of the large glands. In March, 1898, the ulcer had spread from the anterior to the posterior border of the axilla and was 1½ in. broad. There were a nodule on the pectoral muscle, a large mass on the axilla, and glands in the neck, one of them of the size of a walnut. The patient suffered great pain and had to have frequent doses of morphia. The second case, a woman, aged thirty-three years, was admitted to King's College Hospital on May 23rd, 1897, with cancer affecting both breasts. It was clearly a case in which no radical operation could be performed with any chance of success. Accordingly on May 26th both ovaries and tubes were removed. By June 19th there was thought to be slight improvement, but this was not maintained. Her condition steadily grew worse, internal deposits in the liver and probably also in the pleuræ appeared, and she died towards the end of October. In the first case oöphorectomy appeared to have had a marked effect on the growth of the cancer at first, but at the end of six months the disease began to grow again and since had made great strides. Mr. Watson Cheyne held it clear that there is a distinct connexion between the normal epithelium of the breast and the ovaries and also between cancerous epithelium of the breast and the ovaries. But unfortunately in all the cases it appeared that the effect of the removal of the ovarian influence is only more or less transitory, whilst in many cases no effect is produced at all. In future cases it might be well to remove at the same time as the oöphorectomy, or possibly later, as much of the noticeable disease as possible.—Mr. HAROLD STILES of Edinburgh said that those who had had the opportunity of seeing Dr. Beatson's first case felt that his treatment was based on well-established scientific fact. But, unfortunately, in no case had the patient been permanently freed from the disease by removal of the ovaries. Dr. Beatson a few days previously had given him (Mr. Stiles) an opportunity of seeing his first case, in which, after complete disappearance of the disease for several months recurrence had become manifest. In the Edinburgh Royal Infirmary Dr. Beatson's treatment had been carried out by more than one surgeon with the result that in some cases the disease had been temporarily arrested, whilst in others it had been uninfluenced.—Mr. ALBAN DORAN noted that Dr. Beatson laid down a rule of treatment which was that a cancerous breast should be removed early and if recurrence took place the ovaries should be taken away, the thyroid treatment being also necessary if the patient were near the menopause. Dr. Beatson admitted that his treatment was useless if secondary deposits had developed. If the greatest amount of good be sought it is clear, Mr. Doran insisted, that each ovary must be completely removed. He knew from experience that to do so and leave a safe pedicle was not always easy even if both ovary and uterus were normal. He described his method of removing ovaries for the relief of fibroids; the ovarian ligament was transfixed close to its uterine attachment. Unfortunately the stump of that ligament sometimes contained ovarian tissue. In Stanley Boyd's fourth case, where the patient was over sixty years of age, the ovaries had undergone extreme atrophy. Their removal for the suppression of an influence which they had ceased to exert naturally proved useless. Altogether Mr. Doran was not surprised to hear of the ill-success of oöphorectomy in inoperable cancer since he was never certain that all ovarian tissue could be removed nor were the advocates of the method certain that perfect extirpation ensured perfect cure. The mere operation might cause somehow the temporary arrest of the cancer, just as abdominal section was sometimes followed by parotitis without evidence of sepsis.—Mr. MALCOLM said there seemed to be little doubt that a simple exploratory incision into the peritoneal cavity was occasionally followed by a temporary diminution of size of a malignant abdominal tumour. The improvement of cancerous mammary growths after oöphorectomy appeared to be also temporary and did not always follow this operation. It had occurred to him that the cause of the improvement in these two cases might be similar although as yet unexplained.—Mr. WATSON CHEYNE, in reply, said that in his two cases he had completely extirpated the ovaries and was certain that no ovarian substance was left behind. He thought that the disappearance of lumps in the abdomen which had been mentioned was accounted for by their being

inflammatory and not malignant. It was difficult to explain the good results which occasionally followed simple laparotomy. He alluded to Dr. Lauder Brunton's recent advocacy of laparotomy in cases of pulmonary phthisis.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A MEETING of this society was held at the London Institution on April 13th, the President, Mr. COTMAN, being in the chair.

The following cases were exhibited:—

Mr. JOHN ADAMS: 1. A child with an Extensive Scar on the Face and loss of the Digits of both Hands except the Left Thumb. There was no history of the case and the exhibitor attributed the lesions to Raynaud's disease. 2. A girl, aged eighteen years, with Congenital Heart Disease. There had been no hæmoptysis and the area of cardiac dulness was very wide on the right of the median line.

Sir HUGH BEEVOR: Two cases of General Alopecia which had been treated with Thyroid extract; in both instances marked improvement had occurred.

Dr. F. J. SMITH: Two cases of Primary Myopathy affecting the Legs of young men. There were no sensory disturbances and the electrical reactions were normal in quality though diminished in quantity. No reaction of degeneration. There was no family history of any similar disease.

Dr. SEQUEIRA: A case of well-marked Pseudo-hypertrophic Paralysis in a child; and a boy, aged seven years, with symptoms of Cerebellar Tumour.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Sanitary Supervision of Elementary Schools.

A MEETING of this society was held on April 15th, Dr. EDWARD SEATON, President, being in the chair.

Dr. REGINALD DUDFIELD read a paper on the Sanitary Supervision of Elementary Schools with Special Reference to the Spread of Infectious Diseases. There was no denying the general overcrowding of these schools which was favoured by the regulations of the Education Department. The superficial and cubic space per head required for calculating the accommodation of a school was far too small; while 350 cubic feet was the lowest allowance in factories 120 was fixed by the Department for schools, which to maintain a purity of 0·2 per 1000 of CO^2 would demand a renewal of the air twenty-five times in the hour. But even this scanty allowance might be curtailed under certain conditions. This was dependent on the interpretation of the expression "habitual" in Clause 73 of the Code, which stipulated that the average attendance should not habitually exceed the legal accommodation by more than 15 per cent. The intention was to avoid the exclusion of a child from the appropriate class pending redistribution and the drafting of the number in excess to other classes. Memoranda and instructions had been issued interpreting the expression so as to discourage overcrowding, but it was evident that the teachers took it as permitting serious overcrowding during certain months to compensate the scanty attendance in others so long as the *average for the whole year* did not exceed the accommodation by more than 15 per cent., a practice to which the payment to the head teachers of a proportion of the grants still retained in many voluntary schools was a strong inducement. It was, however, clear from Mr. Acland's explanation that the permission extended only to the temporary and unavoidable overcrowding of particular class-rooms which it was the duty of the teacher to relieve as soon as possible by drafting the scholars or redistributing the classes and to occasional aggregations of the children in the principal hall or otherwise. Inadequate, however, as was the cubic space in the schools the conditions of many of the homes were no better, and the gravity of the matter lay rather in the influence of overcrowding on the spread of diseases, among which measles, not notified, widespread, highly infectious, and causing on the whole more deaths than scarlatina and several other fevers put together, was that which had the greatest influence on the attendance, and led most often to the extreme resource of closure and called for serious efforts at its limitation. It was useless to impose the duty of notification on the medical attendant in a disease for which he was rarely called in until alarming complications arose, and parents might plead ignorance; but school-teachers and visitors should notify to the sanitary authority and prompt notification might be made one of the conditions affecting the grant (Section 85), the teacher inquiring into or reporting to the visitor the unexplained absence of any child. He recommended inter-notification between adjacent districts, disinfection of rooms, &c., that exposure of persons suffering from measles should be penal, and that to ensure uniformity the Local Government Board or Education Department should publish a schedule of quarantine periods. Absences under Section 101* might be specially marked in the attendance book. He read letters from Dr. Herbert Peck, medical officer of health of Ormskirk, who found a system of notification imposed on the School Board visitors and requested of the teachers to work admirably, the latter having brought to his knowledge during the past year 247 cases, including several of scarlet fever, of which he had no other intimation. For such notification forms with counterfoils had been drawn up, copies of which were shown.

Dr. PARKES doubted the need for disinfection in measles and thought that infant schools might be closed on the approach of major epidemics.

Dr. NEWSHOLME feared that these could not be foreseen with such certainty as to justify anticipatory closure. But since 75 per cent. of the deaths were of children under six years of age the closure of infant schools would effect a great saving of child-life. He would not, however, have infants under five years of age admitted, though their exclusion would lead to the detention of the older girls at home unless day nurseries were provided everywhere. In Brighton full advantage was taken of Section 101* and the Education Department allowed for the absence of all children in infected houses.

Dr. WILLOUGHBY was inclined to agree with Dr. Parkes as to the impracticability of official disinfection after every case of measles and would rather inculcate thorough house-cleaning and a general wash. He looked on Section 101* as the fruit of his own efforts in this direction, having long urged it in the columns of the *Schoolmaster*, &c. As to the cubic space they might be interested to know that in Ontario the Board of Education, after a scientific study of the whole question, fixed on 250 cubic feet per head and insisted on the adoption of jacketed ventilating stoves on the principle of the Calorigen. He wondered that the London School Board had not introduced the electric light in place of gas which added to the deterioration of the air. In Holy Trinity Schools, Eastbourne, the head-master testified to the great improvement in the air and in the work done in winter afternoons since the change.

Dr. TEW, Dr. CARR and Mr. STOTT spoke of the difficulties encountered in rural districts through the extent of their area and the paucity of sanitary inspectors and School Board visitors. Dr. Tew said that a request for closure, the attendance having fallen off to half, was frequently the first intimation he had of an epidemic of measles, while the others, though they found notification by the teachers to work very well, felt the signing of certificates on the evidence of the teachers or correspondents was not altogether satisfactory.

Dr. JOSEPH GROVES (Isle of Wight) referred to a further difficulty incident to the closure of schools in rural districts bordering on urban which resulted in the permanent loss of the children, who migrated to schools in the towns which remained open.

Dr. S. DAVIES of Plumstead and others having continued the discussion,

Dr. R. DUDFIELD replied and the resolutions he had submitted to the meeting were referred to the consideration of the Council.

LIVERPOOL MEDICAL INSTITUTION.

The Structure and Functions of Nerve Cells.—Pulmonary Tuberculosis.—Exhibition of Specimens.

A MEETING of the Pathological and Microscopical Section of this society was held on April 21st, Dr. ROBERT S. ARCHER being in the chair.

Dr. GRÜNBAUM gave a demonstration of the Spectra of

Hæmoglobin and its chief derivatives, with special reference to the properties of Carbon-monoxide Hæmoglobin.

Dr. WARRINGTON read a communication on the relation existing between the Structure and Functions of Nerve Cells. He showed that certain cells of the anterior cornua undergo a distinct structural change after the withdrawal of the afferent impulses which normally impinge upon them through the posterior roots. He also illustrated the changes which occur in nerve cells after division of their axis cylinders. He discussed the possibility of a *restitutio ad integrum* in certain cases, pointing out that whereas, if examined soon after a lesion, most of the corresponding cells show distinct changes, if a long interval is allowed to elapse the group of cells is found normal or, at any rate, only a few cells are atrophied. The communication was well illustrated by numerous specimens and by excellent drawings and micro-photographic lantern transparencies. — Dr. A. W. CAMPBELL congratulated Dr. Warrington on the capital piece of work he had concluded and said that notwithstanding all the work which had been done on the subject by the very best workers, never, in his opinion, had the connexion between the posterior root fibres and the anterior cornual cells been so beautifully demonstrated as in the specimens exhibited that evening. He thought the method employed should be extended to tracing out other connexions between spinal tracts.—The paper was also discussed by Dr. ARCHER, Mr. DAMER HARRISSON, and Dr. IMLACH.

The SECRETARY (Mr. Larkin) presented, on behalf of Dr. BUCHANAN, who was absent on account of illness, a paper entitled "Observations on Pure and Mixed Infections in Pulmonary Tuberculosis in Relation to Prognosis." The paper was accompanied by a careful analysis of 21 cases and was profusely illustrated by microscopic specimens. The paper was accepted and ordered to be published in the Transactions and a vote of sympathy with Dr. Buchanan was unanimously passed.

In addition to the numerous specimens illustrating the above communications the following were shown:—

Dr. BARENDT (for Dr. PERMEWAN): (1) A Pedunculated Fibro-myxoma removed by Subhyoid Pharyngotomy from the upper end of the Œsophagus of a woman, aged forty-six years; and (2) Large Portions of Greatly Enlarged Inferior Turbinate Bones, which had produced complete nasal obstruction, for the relief of which they had been removed.

Dr. BRADSHAW and Mr. THELWALL THOMAS showed a piece of Small Intestine which two days before death had been the seat of suture for a perforation. The patient was suffering from typhoid fever which had run a severe course of from seven to eight weeks, but the temperature had become almost normal. The operation was performed thirty-six hours after the symptoms of perforation appeared. Death took place apparently from exhaustion; no leakage had occurred.—Dr. ARCHER remarked that he had seen several cases of perforation in enteric fever and that four days seemed to be the limit of time that patients lived after its occurrence. As this patient died on the fourth day the operation did not seem to have either shortened or prolonged life. He understood that some 19 cases of this operation had been placed on record. Of these 4 had recovered, but 3 of these were probably not enteric at all.

Mr. C. THURSTAN HOLLAND showed Radiographs of, and Bones from, a Foot amputated by Mr. Robert Jones for an ulcer occupying the whole sole in a man, aged twenty-four years. There were no signs of nervous disease. The ulcer had existed five years and no dead bone had ever come away, but whilst the tarsus was complete the metatarsals and phalanges were only represented by small misshapen fragments of bone.

Mr. R. W. MURRAY showed (1) a Hydrocephalic Brain in which he had attempted to establish a communication between the ventricles and the subdural space; and (2) a case of Imperforate Anus and Congenital Stricture of the Left Ureter. The ureter above the stricture was so much dilated that it was mistaken for the bowel and opened.

Mr. LARKIN showed: 1. An Intra-articular Tumour of the Left Knee which he had recently removed from a man, aged thirty-five years. It commenced after an injury to the knee and gave rise to symptoms resembling those of a loose body. It was attached in front to the internal alar ligament and projected thence backwards between the bones. It measured 2½ in. long, 1½ in. broad, and ¾ in. thick. 2. A water-colour sketch of a peculiar variety of Imperforate Anus, in which a canal passed forward from the anal dimple along the perineum and scrotum to the penis, where it opened by a pinhole aperture discharging meconium. The urethra was normal. 3. A Persistent Vitello-intestinal Duct opening at the umbilicus and through which an intussusception had occurred.

Mr. NEWBOLT showed (1) an Adeno-sarcoma of the Breast; (2) Carcinoma of the Penis; (3) Cystic Tumour of the Jaw; and (4) a Varicose Vein 24 in. long.

Dr. IMLACH exhibited some models which he had constructed of the Spinal Cord showing the various ascending and descending tracts and their relation to the cerebral centres. He saw, he thought, that the use of such models instead of diagrams would materially simplify the study of nervous cases and enable the practitioner to compare the facts of degeneration which had been ascertained by Waller and his school with the tracts of sclerosis due to disease.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Pathological Changes in Nerve Cells.—Diagnosis of Pathological Conditions of the Endometrium.—Pathology of Fissure and Ulcer of the Anus.—Exhibition of Specimens.

A MEETING of this society was held on April 13th, Dr. BROOKE, Vice-President, being in the chair.

Dr. WARRINGTON (Liverpool) read a paper on the Pathological Changes in Nerve Cells and gave an account of some investigations which he had been conducting. He showed that marked changes occurred in the anterior cornual cells of the spinal cord after cutting off the afferent impulses which impinge upon them. The affected cells were chiefly found in the postero-external group and in that segment of the cord the afferent and efferent roots of which are specially concerned with innervation of the foot. He also mentioned and illustrated the recent changes which occur in a nerve cell after division of the axon belonging to it and showed in the case of the spinal cord that after section of an anterior root almost every cell on the side of the lesion of the affected segment gave evidence of distinct change in its structure. The paper was illustrated by a large number of drawings, microscopic sections, and lantern slides.

Dr. ARNOLD LEA read a paper on the Diagnosis of Pathological Conditions of the Endometrium, illustrated by microscopic sections and lantern slides, with special reference to the value of the microscope in the diagnosis and treatment of these affections, and pointed out the limits of its usefulness. The diagnosis of previously existing intra-uterine pregnancy can generally be made with certainty from the examination of curetted fragments. Chorionic villi may be recognised many months after the death of the ovum; decidual cells are not absolutely diagnostic, as similar cells are found in some forms of chronic endometritis, membranous dysmenorrhœa, and in the cast of extra-uterine gestation. The large glandular spaces, remains of the decidua vera, are of great value if present. In chronic glandular endometritis the mucous membrane is swollen, smooth, and softened; the glands are multiplied, enlarged, and very tortuous, the proliferated epithelium may fill the lumen and in the deeper parts solid epithelial buds may be recognised, an important fact, as this is held by some as evidence of malignancy. The stroma shows round-celled infiltration. In old cases atrophy of all the constituents of the endometrium occurs. The so-called "villous polypoid or hæmorrhagic endometritis" is rather a diffuse benign adenoma, inflammatory changes being often absent; the growths are simply glandular, very vascular and occasionally single and pedunculated. Sections of fibro-adenoma were also shown. The use of the microscope in differentiating simple inflammatory, benign, and malignant, growths is of great value; carcinoma is easily recognised, but malignant adenoma may closely simulate benign growths, the chief points of distinction being that (1) many alveoli may be completely filled with epithelial cells; (2) the glandular spaces are very numerous, much branched, and are often arranged in parallel columns; (3) the amount removed by the curette is more abundant; and (4) the growth infiltrates the muscular coat, so that in examining curetted fragments unstriped muscular fibre may often be recognised. In some few doubtful cases microscopic evidence may need to be supplemented by clinical signs before a diagnosis can be made.

Mr. J. E. PLATT made a communication on the Pathology of Fissure and Ulcer of the Anus. After referring to a few

points in the anatomy of the lower end of the rectum, more particularly the form of the anal valves and the free distribution of branches of the inferior hæmorrhoidal nerves to the muco-cutaneous junction, he stated that two distinct affections having a different pathology are described together in text-books as fissure and ulcer of the anus. He gave the following account of these conditions: 1. In a large proportion of the cases the lesion is situated at the junction of skin and mucous membrane and generally takes the form of a vertical fissure, most frequently situated at the dorsal part of the anus. It is produced by undue stretching or excoriation of the part and amongst its causes are the passage of hard fæces, severe diarrhœa, want of cleanliness, eczema, syphilis, laceration during child-birth, and congenital stenosis of the anal outlet. The affection is extremely painful owing to the very free nerve-supply of the muco-cutaneous junction. Not infrequently one or more nerve-filaments are exposed in the base of the fissure. The pathology of the affection is that which is usually described as applicable to all cases of fissure and ulcer of the anus. From constant irritation reflex spasm of the sphincter muscles is set up and thus healing is prevented. 2. The second affection is situated, or at all events begins, at the upper part of the anal canal and is due to a tearing down of one of the anal valves. As a result of this a raw surface is produced, healing is prevented by the frequent opening of the wound during the passage of fæces and an ulcer, round, triangular or V-shaped, results. The torn-down valve becomes œdematous and indurated, thus giving rise to the "sentinel pile" so often met with in these cases. This view of the pathology of fissure was first advanced by Mr. Ball of Dublin. It undoubtedly holds good for one class of cases, but it is by no means applicable to all. Reference was also made to certain differences in the symptoms and the treatment of the two conditions.

The following card specimens were exhibited:—

Dr. HARRIS: (1) Aortic Aneurysm; and (2) Thyroid, &c., from Exophthalmic Goitre.

Mr. HIGGINSON: Two cases of Extra-capsular Fracture of the Femur.

Dr. LEA: (1) Uteri removed for Multiple Fibroids; and (2) Uterus and Appendages removed for Gonorrhœal Inflammation.

Dr. LEECH: Ulcerative Entero-colitis.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Peritonsillitis.—Cephalic Tetanus.

THE ordinary monthly meeting of this society was held on March 30th, the President, Dr. ARNOLD EVANS, being in the chair.

Dr. KURICH gave a Microscopical Demonstration.

Dr. GLADSTONE showed: (1) A case of Myxœdema treated with thyroid gland; and (2) a Specimen of Meckel's Diverticulum.

Dr. CAMPBELL exhibited the Kidneys from a case of Cerebral Hæmorrhage in a boy aged fourteen years. The illness commenced suddenly with an attack of nausea followed by vomiting. The patient then had a fit and three hours from the commencement was comatose with Cheyne-Stokes respiration. The reflexes were brisk and the optic discs were blurred. There was no paralysis. The patient died from respiratory failure after six hours' illness. On post-mortem examination there was extensive hæmorrhage into the brain cavities, but not into the cerebral substance. The pericardium was adherent and the heart was hypertrophied. The kidneys were much enlarged and showed the changes of congenital cystic disease, together with those of chronic parenchymatous nephritis.—Professor TREVELYAN and Dr. WOOD discussed the case and Dr. CAMPBELL replied.

Dr. BRONNER read notes on Peritonsillitis. He pointed out that the tonsil may or may not be enlarged and that there is often present disease of the surrounding cavities, e.g., carious teeth. Œdema of the tissues about the tonsil indicates the presence of pus which usually points above. The pus should be evacuated by puncture about the middle of a line drawn from the base of the uvula to the upper wisdom tooth. Pain in the ear is often a prominent symptom and there is often tenderness over the tip of the mastoid process. In the after-treatment enlarged tonsils should be removed or the diseased lacuna slit up. Any disease of the accessory cavities should be treated.—Dr. HALL drew attention to hæmorrhage and to septicæmia as complications of tonsillitis. The hæmorrhage might occur independently of any incision.—Dr. MAJOR, Dr. WOOD, and Mr. BERESFORD offered further remarks and Dr. BRONNER replied.

Dr. BASIL HALL read notes on a case of Cephalic Tetanus. The symptoms appeared on the fifth day, after a wound in the malar region. The patient was treated from the beginning with chloral hydrate and on the fourteenth and subsequent days injections of antitoxic serum were given. He was discharged cured on the thirty-fourth day.—Professor TREVELYAN drew attention to the presence of paralytic symptoms as the distinction between cephalic and ordinary tetanus. He thought that if the antitoxin treatment were to be successful the serum used must be of high potency.—Dr. WOOD offered further remarks and Dr. HALL, in replying, doubted if the antitoxin had much to do with the patient's recovery.

Diagnosis.

A special meeting of this society was held on April 1st, the President, Dr. ARNOLD EVANS, being in the chair.

Dr. PYE-SMITH gave an address on Diagnosis. Alluding to the extreme importance of diagnosis in the practice of medicine Dr. Pye-Smith pointed out that this importance has only been recognised comparatively recently and that the older physicians were content to regard symptoms such as dropsy and apoplexy as diseases. The introduction of physical examination, combined with the study of morbid anatomy, at the beginning of the present century led to the comparison of the physical conditions as determined at the bedside with those found in the body after death, and thus a firm basis was established on which the relations between physical signs and diseased conditions could be determined. Dr. Pye-Smith insisted that the physicians should not be satisfied till a diagnosis in any case had been made and written down, the diagnosis to be made deliberately after due examination and not on mere superficial considerations. In complicated cases it is sometimes necessary to neglect some details while grasping the salient points and this could only be done by practice and insight. It is often necessary to fix on some important objective symptom and not to be too much influenced by history and subjective symptoms, which are often very misleading. It may be necessary to make a diagnosis gradually, the different steps being only attained after the lapse of time. Assuming a diagnosis to have been made, it may be that the treatment proves ineffective or the prognosis is shown to be inaccurate. It is then best to go over the whole case afresh, when some symptom or sign not existing or not detected at the previous examination may become evident, thus throwing a new light on the whole case. A diagnosis, especially in writing death certificates, must not be pushed beyond what the facts warrant in the absence of a post-mortem examination. Dr. Pye-Smith alluded to the consideration of diagnosis in insurance reports and pointed out that death from "childbirth" often might mean phthisis; or from "jaundice" or "dropsy" intemperance. Judgment in coming to a diagnosis depends largely on a knowledge of pathology and it must be assumed broadly that the common things commonly occur. The use of surgical interference to make a diagnosis was deprecated until the other methods at the command of the physician have been exhausted.

A vote of thanks, moved by Dr. EVANS, seconded by Mr. MAYO ROBSON, and supported by Dr. ALEXANDER, was carried.—After the address a dinner was held, at which Dr. PYE-SMITH and about fifty members of the society were present.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Intestinal Resection.

A MEETING of this section was held on April 1st, Mr HENRY GRAY CROLY being in the chair.

Mr. JOHN LENTAIGNE detailed three cases of Acute Intestinal Obstruction from Malignant Disease which he had

treated by the formation of an intestinal fistula, at a point above the obstruction, so placed as to be least likely to interfere with a subsequent operation for radical cure of the disease. As the seat of disease in each of the three cases was the sigmoid flexure the fistula was made in the cæcum. In the first case the bowels resumed their normal function eleven days after the completion of the intestinal fistula; the latter then gradually closed of itself. Nine months later the patient came back to the hospital. The fistula had then reopened and the bowels were acting freely through it. Large masses of cancer could be felt through the abdominal wall. This patient died thirteen months after the operation. In the second case an operation for radical cure by resection of the cancerous mass, with end-to-end anastomosis after the method recommended by Professor Kocher, was performed three months after the fistula had been completed. The patient had enjoyed excellent health ever since and as two years had elapsed since the resection it was not unlikely that a complete cure had been effected. In the third case the patient had delayed very much longer, not returning until eight months later. She was anxious to have something done and an exploratory laparotomy was performed. It was found that the disease had spread far and wide and was absolutely inoperable; the abdomen was closed and the patient left the hospital shortly after, the bowels acting freely through the fistula. She was no better for the last operation, but neither was she any the worse. Celloidin was of great use as a dressing in effectually preventing contamination by discharges from the fistula. The cæcal fistula was quite as efficient as an artificial anus and much more satisfactory inasmuch as it closed of itself when the obstruction below it was removed.

Mr. GORDON read a paper on a case of Hæmorrhagic Infarction of the Small Intestine which he had treated by resection. The leading symptoms were: (1) sudden onset, marked by severe abdominal pain; (2) vomiting; (3) prostration bordering on collapse; and (4) a tumour formed by a distended coil of gut, easily palpated in the right iliac region. There was no general abdominal distension. Operation was performed twenty-four hours after the onset of pain. Much bloody fluid was found in the abdomen and the coil of distended bowel was black. Two feet of small intestine were resected, together with an area of mesentery. The ends of the gut were united over a bone bobbin. An intestinal fistula formed ten days later, but had completely closed at the end of three weeks from the date of operation. This was in August 1897, and up to the present there had been no evidence of abdominal trouble.—Mr. WHEELER said it was fortunate that bobbins would probably be required no longer since the discovery of Maunsell's method. He had lost two cases in which he had used Murphy's button, to which he thought the result was due. The best result of excision of the large intestine he had ever seen was obtained by the late Dr. Kidd, and he, having excised about six inches of bowel, sutured the bowel over a scoop cut out of a piece of carrot.—Mr. HARRISON SCOTT, Mr. R. GLASGOW PATTESON, and Mr. HENRY GRAY CROLY also discussed the cases.

SECTION OF MEDICINE.

Cerebral Abscess.—Typhoid Fever.

A MEETING of this section was held on April 15th, Sir GEORGE DUFFEY, the President, being in the chair.

Mr. J. J. BURGESS read a paper on a case of Cerebral Abscess.—Dr. E. H. BENNETT thought the specimen a rare one of chronic abscess of the brain, existing and giving sufficient characteristic symptoms for over two years. Probably a blood-clot in the arachnoid was the primary lesion and suppuration took place in it. He thought that operative interference would have had a bad result in the case.—Dr. FALKINER asked Dr. Bennett why he thought that operative interference would have produced a more rapidly fatal result. He himself would have been in favour of surgical interference.

Dr. FINNY read notes on a case of Laryngeal Ulceration in the Advanced Stage of Typhoid Fever.

Dr. H. C. DRURY read a paper entitled "Some Remarks on Typhoid Fever." He expressed the opinion that the occasional use of mild purgatives at any stage of the disease, where indicated, was not only harmless but beneficial. He also discussed the question of the time to give solid food and said that in average cases a small quantity of fine farinaceous food might be given on the fourth day. He thought, also, that too much routine was followed by insisting on the use of the bed-pan in all cases. So many patients found its use difficult or intolerable that it was more likely to do harm than a night-chair, the use of which was always easier, and he had never seen it followed by any bad result. He quoted statistics from Cork-street Fever Hospital, where all these practices were followed, to show that he was justified in stating that they were in no wise harmful but rather beneficial.—Dr. LITTLEDALE said that with the Widal reaction there were two kinds of motion—molecular motion, which occurs in most typhoid fever cases for half an hour, and true motion, which, as a rule, is not seen in typhoid fever cases. As regards clumping, in cases of typhoid fever after a clump is formed a bacillus will never leave a clump, whereas in other non-typhoid fever cases two or three bacilli will leave the clump and go across the field. He thought that the Widal reaction sometimes left one in doubt. In ordinary cases he was disposed to think that they diluted too much.—Mr. BURGESS agreed with Dr. Drury regarding the treatment of typhoid fever with purgatives. He had tried purgatives for many years and never found any bad results.—Dr. J. W. MOORE agreed entirely with the treatment by purgatives. Calomel was the best aperient in the earlier stages, from two to five grains in the first week of the fever.—Dr. W. G. SMITH said that he was in favour of aperients in constipation, as the latter tended to precipitate perforation. He gave castor oil and calomel by the mouth and enemata when necessary.

Reviews and Notices of Books.

Ambroise Paré and his Times. By STEPHEN PAGET. Illustrated. New York and London: G. P. Putnam's Sons and the Knickerbocker Press. 1898. Pp. 304. Price 10*s.* 6*d.*

IT is easy to understand Mr. Stephen Paget's enthusiasm for the great French surgeon of whose picturesque life and times he has given an excellent account in these pages There are few more attractive personalities than that of Ambrose Paré; his life was full of adventure and romance and he reveals in his own story of his life a character delightfully compounded of simplicity, shrewdness, and humour. As a surgeon he was the type of the practical man, not caring greatly about theory in which he was little, if at all, ahead of his time although far above all his contemporaries in practice. His extreme attention to details and his remarkable fertility of resource in devising methods of treatment were probably the great secrets of his success. They are illustrated at every turn in his own writings from which his present biographer has wisely drawn largely, thus allowing him in great part to be his own biographer. Paré's life (1510–90) almost covers the sixteenth century. The history of France during that century is one of the most picturesque and romantic periods of all history. Paré during his life of eighty years saw seven successive occupants of the French throne, from Louis XII. to Henri IV., and was surgeon-in-ordinary to four of them. The history of their reigns is one of almost incessant warfare, at first against an alien enemy and later nearer home in the long internecine struggle between Catholics and Huguenots. There was no lack of work for the army surgeon in those days and rather more than his share of it fell on Ambroise Paré's capable shoulders. His earliest experience of war was at the attack of Turin in 1537, an account of which forms the first chapter of his famous "Journeys in Diverse Places." It was in this expedition that he was horrified by the barbarous practice then in vogue of treating gunshot-wounds by pouring in boiling oil, and he substituted for this the more humane method of applying "a digestive made of the yelks of eggs, oil of roses and turpentine." This and all his succeeding "Journeys"

are excellent reading—full of good stories, but more especially attractive from the naïve manner in which they are told and still more naïve marginal notes of the author. In those notes he stops every now and then to encourage himself with such remarks as "Témoignage de la dexterité de l'autheur," "Addresse de l'autheur," or "Charité de l'autheur." His quite delightful vanity may be readily forgiven him; without it we might never have had these entertaining stories. He wrote the book in answer to one Etienne Gourmelen, who had asserted that "Paré's revived use of the ligature was inferior to the old-established use of the cautery in amputation wounds." He tells the story of all his campaigns to prove that his knowledge was gained in hard practical experience and that compared to it the book knowledge and theory of his adversary was mere prating pedantry. He never tires of reminding poor Gourmelen of this at every opportunity, always in good temper, however, and often with no little humour.

Paré published several other books—works on Surgery, Anatomy, Gunshot Wounds, the Plague, and Obstetrics. Mr. Paget urges his readers to study Paré at first hand in his own writings. We can warmly recommend this volume as an introduction and guide to anyone following the advice. The author has gathered together a large number of detailed facts concerning his hero's life and illustrating his character, and these should whet the reader's appetite for a closer acquaintance with his works. The interest of the volume is enhanced by the large number of illustrations which it contains; these include portraits of Paré himself, of several French sovereigns and other contemporary celebrities, views of old Paris, blocks of surgical instruments taken from Paré's works, and a remarkable block showing a method of reducing dislocation of the humerus.

Practical Toxicology for Physicians and Students. By Professor Dr. RUDOLF KOBERT. Translated and edited by L. H. FRIEDBURG, Ph.D. New York: William R. Jenkins. 1897.

KOBERT'S "Compendium of Practical Toxicology" is properly recognised as a standard work, and an English translation which appears as a first American edition will be welcomed. Among the chief features in Dr. Kobert's work are the excellent tables, which in themselves give at a glance the characteristics of poisons, chemical and clinical, and the course to adopt when there is a possibility after the poison has been recognised of the saving of the life of the individual. The book, though not a large one, is very comprehensive. The translator, in his lectures and demonstrations at the American Veterinary College, New York, as well as at the Flower Hospital Medical College, has adopted Kobert's Compendium as a standard work of reference. The tables in particular prove valuable and from a student's point of view convey "all they cared to know." We are glad that Dr. Friedburg was not tempted by this pronouncement to give a translation simply of these tables or of abstracts of them. This course would have been manifestly unfair to the author. As it is, the work, translated in its entirety, is one that will prove valuable to toxicologists for reference, whether they be students or men engaged in everyday practice. The book is an excellent example of the power of concentrating facts within easy compass without sacrificing their importance. The work is divided into three sections: (1) general toxicology, (2) special toxicology, and (3) an appendix. The first section relates to the definitions of poison, to the etiology, diagnosis, and prognosis of poisoning. Antidotes are here also referred to and an interesting chapter is added on the pathological demonstration of poisoning. This is followed by an admirable *résumé* of the methods employed for the chemical and physiological detection of poisons. The section on special toxicology relates to substances which cause "grave anatomical changes" of the organs such as corrosives, to blood poisons such as phallin and substances like the poisons of the cerebro-spinal system which may prove fatal without causing any specific anatomical indications. The appendix is a very valuable contribution, consisting of a review of the toxicologically interesting products of metabolism. This of course includes animal and vegetable esculents and the poisons occurring occasionally in sausages, meat, and cheese. The book is full of "Americanisms," of which the heading in one instance—namely, Table of Intoxications by the Most Important Tetanics—is a fair sample. The nomenclature adopted is again that of the American Association for the Advancement of Science, 1891. Although these may be a source of irritation to the English reader in England it does not detract from the merits of the book, which are considerable. The book is indeed a valuable addition to the literature of toxicology.

A Text-book of Practical Therapeutics. By HOBART AMORY HARE, M.D., B.Sc., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; Physician to the Jefferson Medical College Hospital, &c. Sixth edition. London: Henry Kimpton. 1897. Pp. 758. Price 21*s.*

THE fact that this work has passed through five editions in seven years, and that a sixth is now called for, is sufficient evidence that not only has a want been supplied but that the author has been successful in his endeavours to carry out his intention of producing a work on therapeutics which should teach a distinct practical application of remedial agents in the treatment of disease and their employment upon a rational basis.

The book is divided into four parts. Part I. is concerned with general therapeutical considerations, modes of administering drugs, dosage, strength and reliability of drugs, classification of drugs, &c.

Part II., which occupies the main part of the work, is simply headed "Drugs," and contains a full description of the various mechanical agents included under that term, together with their therapeutic measures. This portion is worthy of the highest praise. After a technical description of the drug, its source and preparation, follows its physiological action on the various systems of the body; then the modes of its elimination; next any peculiar properties, such as an antiseptic action or toxic changes from prolonged use, &c. Then we find the symptoms of poisoning and the measures to be adopted should such an occurrence present itself. The therapeutics are very plainly and fully considered and conclude with "untoward effects" (if any). Then follow the methods of administration, the doses being given according to the two systems in vogue (apothecaries' and metric), and finally are the "contraindications" for the use of each drug.

In Part III. are described remedial measures other than drugs and a description of the methods employed in preparing foods for the sick.

Part IV. commences with a consideration of the various diseases purely from a therapeutic point of view. Here also will be found a large amount of useful information. In conclusion various tables are given—namely, "doses of medicines," "tables of relative weights and measures in the metric and apothecaries' systems"; index of drugs and remedial measures and index of diseases and remedies.

We can thoroughly recommend this book to practitioners and students.

Surgical Pathology and Principles. By J. JACKSON CLARKE, M.B. Lond., F.R.C.S. Eng. London: Longmans, Green, and Co. 1897. Price 10*s.* 6*d.*

THOSE students who have had the benefit of Mr. Jackson Clarke's oral instruction will be glad of this embodiment of

it in permanent form. He has condensed into a comparatively small compass a large amount of fact in connexion with surgical pathology, surgery, and allied subjects. It is presented plainly, if summarily, and, as might be expected from the author's knowledge and experience in teaching, prominence is chiefly given to those matters which are of the greatest importance. It is, moreover, sufficiently accurate and up to date. Such a book will doubtless be useful to the student who is preparing for examinations and has therefore its justification. The writer has, however, in our opinion attempted too much; his professed aim has been to present not only the facts of surgical pathology but the principles of their application to surgery, and he has gone beyond this and introduced no small amount of symptomatology and even details of treatment. Thus in the short section on diseases of the eye little room has been left for their pathology in the true sense of that term. Under the heading of tumours of the brain a short indication of the nature of the commoner tumours is given, followed by a here unnecessary epitome of their symptoms which includes an incomplete definition of Jacksonian epilepsy but no account either of its pathology or of the pathology of any other symptom. Under the heading of leukæmia, which has, by the way, very doubtful affinities with Hodgkin's disease, the description of the blood changes is entirely inadequate. In a work of this kind bacteriology should either be omitted or more fully dealt with. Koch's postulates require to be explained to a student, not merely baldly stated, and such difficult problems as immunity are not to be passed over with so little ceremony as is here the case. The book, in fact, good as it is in many respects, would have been vastly better if the author had limited himself more strictly to true pathology; if he had explained more even at the cost of stating less. The numerous illustrations, though not wanting in clearness, are sometimes crude and occasionally inartistic. The etymology of many words derived from the dead languages is well explained, but we must point out that empyema is incorrectly spelt "empysema." The defects which we have felt it our duty to mention are nevertheless outweighed by the large amount of useful and well-presented surgical fact which Mr. Jackson Clarke has succeeded in condensing into small compass for the use of the student.

Vade Mecum of Ophthalmological Therapeutics. By Dr. E. LANDOLT and Dr. P. GYGAX, translated by Dr. E. NEYMAN. London and Philadelphia: J. B. Lippincott Company. 1898. Pp. 138. Price 3*s.* 6*d.*

THIS handy little volume will be found very serviceable by practitioners who may require, without having the opportunity of referring to the larger ophthalmic works, to improvise the means of treatment of any of the ordinary diseases of the eye. It is entirely devoted to therapeutics; there is no hint of diagnosis or any description of the course of the different affections to which the eye is liable. It is presumed throughout that the surgeon recognises the disorder and only wishes to be reminded of the means at his disposal for its relief or cure. The subjects are treated of in alphabetical order, and whilst on the one hand the several drugs and their doses and effects are given, on the other hand the various diseases are mentioned, with the drugs which have been found to be serviceable in their treatment and upon which experience has shown that reliance can be placed. The doses are given both in the French metric and in the English apothecaries' weights. An example or two will best show how the subjects are treated. Turning to cyclitis we find: "Rest, atropine (23 a), poultices (255), diaphoresis (305), purgatives, smoked glasses. For the pain: morphine (231 c), strengthening treatment, iron (164), and iodine (147) preparations. In case of synechiæ: iridectomy as soon as inflammation has subsided." The numbers refer to other articles. We find accordingly under 23 a: "Neutral sulphate of atropine 0/05 = ½ grain. Distilled water 10/00 = 2½ 5." Three other formulæ for atropine lotions are appended. After these have been given the following remarks are made: "To get the *greatest possible effect* introduce the pure salt into the conjunctival sac, taking care to close the lacrymal ducts by pressure. As a rule let the patient keep the eyes closed for five minutes after having instilled the mydriatic. In case of poisoning by atropine, (*a*) absorption *per os:* stomach-pump or hypodermic injections of a solution of hydrochlorate of apomorphine 2 : 1000 up to 30 centigrammes (5 grains); (*b*) absorption *through the tissues* (injections): hypodermic injections of a solution of hydrochlorate of pilocarpin 5 : 100, repeated as often as necessary up to 60 centigrammes. In *both* cases *internally:* brandy, strong coffee, carbonate of ammonia (10 b)."

The number of entries is no less than 326 and as far as we have consulted the work the remedies seem to be thoroughly reliable. Had we space we should have liked to reproduce the article on Keratitis, which is exceedingly well done.

Prilosis or "Sprue"; its Nature and Treatment, with Observations on Various Forms of Diarrhœa acquired in the Tropics. By GEORGE THIN, M.D. St. And. Second edition. London: J. & A. Churchill. 1897.

OUR knowledge of tropical diseases of the alimentary canal is still so imperfect that all students of the subject will welcome the appearance of a new and enlarged edition of Dr. Thin's well-known monograph on psilosis. The diagnosis and treatment of this malady are already placed on a fairly firm basis, but as to its etiology and true pathology we are still almost in the dark. Dr. Thin's researches in the field have been important and are well set forth in the present volume. In the earlier chapters the symptoms, geographical distribution, and diagnosis of the disease are considered. The literature of the subject and the different varieties of psilosis are next reviewed. The author gives sufficient reason for separating true psilosis from ordinary tropical diarrhœa, relying especially on the tongue symptoms in early stages of the disease. The pathological changes which have been observed are fully reported, including the two cases which were minutely investigated for the author by Dr. Wethered, particulars of which have been already published. In the chapter on etiology such bacteriological examinations as have been made are described, and we can only regret their incompleteness and inconclusiveness. In the matter of treatment Dr. Thin is in accord with other authorities on the subject, rigid diet being the essential factor. Not the least important part of the book will be found in the appendix, in which some 30 selected cases are fully described. It is from a study of these cases that the author's conclusions may best be justified. Some valuable coloured plates of the tongue in psilosis complete the book which constitutes an important contribution to the literature of the subject.

On Partial Stationary Cataracts. By HUGO WINTERSTEINER, M.D., First Assistant to the First Ophthalmic Infirmary at the University of Vienna. English edition. Edited by Professor H. MAGNUS. With 20 coloured Plates and text. London: Williams and Norgate. 1898. Price 17*s.*

ALTHOUGH in the numerous pictorial representations of lenticular opacities many forms of stationary cataract have been published, we are not aware that any drawings have been issued dealing exclusively with this form of disease. The author states that all the figures have been reproduced in quintuple linear size, and that he has used for the purpose of examination Magnus's plane mirror with a strong convex lens behind it or transmitted light and Hartman's spherical lens for lateral illumination.

The forms of cataract he has represented are anterior polar cortical cataract, anterior stellate polar cortical cataract, punctated cataract, punctate and stellate perinuclear cataract, central cataract, posterior stellate cortical cataract, cortical æquatorial cataract, traumatic cataract, anterior capsular polar cataract, pyramidal cataract, and secondary cataract after operation for extraction, of which several drawings are given. The whole series are highly finished and are on a scale which permits details to be clearly seen. They are moreover very instructive, not only showing the position and the general appearance offered by each form but also the difference in the aspect presented according to whether the defect is examined by reflected or by transmitted light. The drawings are accompanied by a booklet of explanatory letterpress giving a short account of the history of each case. The notes are perfectly intelligible, but they might have been subjected to the perusal of an Englishman to remove the very obvious indications of translation from the German which they present. The work will prove useful both to general practitioners and to ophthalmic surgeons.

Southall's Organic Materia Medica. Fifth and enlarged edition. By JOHN BARCLAY, B.Sc. Lond., sometime Lecturer on Materia Medica and Pharmacy in Mason College, Birmingham. London: J. & A. Churchill. 1898. Pp. 306. Price 6*s*.

THIS volume is simply what it professes to be, a manual of materia medica, but there is no intention to teach the student either pharmacology or therapeutics, the aim being merely to give him just such information as a person engaged in the handling of drugs might with advantage possess. By druggists and dispensers, therefore, the book will be found most useful, for the descriptions of the drugs and their modes of preparation are well given, and a full index makes it a handy volume of reference. To the medical student, however, for purposes of examination it would be of little value.

The chemical notes are well up to date, while the use of small type in the form of notes dealing with matters of minor importance, such as substitutions, adulterations, allied drugs, &c., has been adopted, it being intended that the reader may thus, to some extent, be guided as to the relative value of the different items of information supplied.

Sewer Gas and its Influence upon Health. By ALFRED H. ROECHLING, C.E. London: Biggs and Co. Price 5*s*. 1898.

MR. ROECHLING has done a good service by collecting together all the evidence in literature and practice relating to the important subject of the connexion existing between sewer air and disease. The poisonous nature of sewer air is still far from completely understood. That it has insidious properties is well known, but its subtle character is not explained by chemical analysis or even by its bacteriology, for, as has been shown by Messrs. Laws and Andrewes in a report to the London County Council, sewer air is practically sterile at least as regards the presence of specific pathogenic organisms. Mr. Roechling has presented these interesting results at some length, while proper emphasis is laid upon the classic investigation of Dr. Alessi. As will be remembered, Dr. Alessi showed that the inspiration of putrid gases predisposes animals to the pathogenic action of even attenuated typhoid bacilli and of bacteria coli. As Mr. Roechling observes these conclusions serve to confirm that which some authors had epidemiologically foreseen and which social hygiene had practically and painfully confirmed. The book contains instance upon instance of outbreaks of typhoid fever being traced to sewer air and immunity from typhoid fever being the case where plans of sewerage and drainage are as perfect as modern construction can make them. Mr. Roechling's work is undoubtedly a valuable contribution on a subject the importance of which cannot be exaggerated. The literature on the relation of sewer air to disease is scattered somewhat broadly, which makes work of reference hard and tedious and unsatisfactory. The present collection of evidence and material is a task which Mr. Roechling has accomplished well and the thanks of all those interested in sanitary advance are due to him.

LIBRARY TABLE.

Sieroterapia. (*The Serum Treatment of Disease.*) By Dr. EMILIO REBUSCHINI. Milan: Ulrico Hoepli. 1898. Pp. 421. Price 3 lire (2*s*. 6*d*.).—This little book, which is one of the extensive series known as the "Manuali Hoepli," gives a useful digest and summary of the various methods of serum treatment which have been employed, as well as of the results which have up to the present time been attained. Original memoirs relating to this subject sometimes become difficult of access for the majority of readers, and the publication of a condensation of them in the present compact and convenient form will commend itself to all who possess even a slight knowledge of Italian. Serum treatment has been applied to upwards of twenty diseases or morbid conditions, diphtheria being, of course, the most important one. Next in order come tetanus, tuberculosis, various streptococcic infections (e.g., erysipelas, puerperal septicæmia, complications of scarlet fever), snake-bite, &c. Dr. Sanarelli's discovery of the bacillus of yellow fever and his immunisation of animals with cultures of it form the subjects of an interesting chapter.

Cookery for Invalids and Others. By LIZZIE HERITAGE. London: John Hogg. 1897. Pp. 184. Price 2*s*. 6*d*.—The list of dishes is copious and well selected, so that no difficulty will be found in providing ample variety to tempt fastidious appetites. The author has not introduced any article which is either troublesome to procure or too expensive for ordinary households and she has made her directions for cooking and serving plain enough to be easily followed. Some will perhaps regret the entire exclusion of cheese, as there are many invalids who can take it in small quantities without inconvenience; either grated or softened by heating with a little milk it is a great improvement to macaroni.

Zur Austilgung der Syphilis. (*The Extinction of Syphilis.*) By Dr. ERNST KROMAYER. Berlin: Verlag von Gebrüder Borntraeger. 1898. Pp. 105. Price, bound, 3 marks 50 pfennige (3*s*. 6*d*.).—The object of this somewhat curious book is to advocate considerable changes in the methods at present adopted by continental nations for the repression of venereal diseases. Dr. Kromayer, who is a *privat-docent* at the University of Halle, argues that it is a delusion to suppose that similar preventive measures are applicable to both gonorrhœa and syphilis, for the majority of prostitutes are never without gonorrhœa, the hospital treatment to which they are subjected does not cure it, medical examination cannot guarantee that a woman does not suffer from it, and any certificate of freedom from it is "a fraud on her patrons" (*ein Betrug des Publikums*), whom she not infrequently infects immediately after having been examined. The medical examination (he says) ought entirely to disregard both gonorrhœa and soft chancre, but syphilis, on the other hand, ought to be dealt with in the most thorough fashion, and he proposes a scheme for the purpose, arranged under nine headings, the principal of which are as follows: everyone who contracts a venereal complaint shall immediately have it diagnosed by a medical man; everyone who is cognisant of another person having a venereal complaint shall advise that person to apply to a medical man and failing compliance shall himself (or herself)

report the case; anyone may claim to be examined without fee by specially appointed medical men, and in the event of syphilis being found shall be entitled to gratuitous treatment. Compulsory examination and treatment are also provided for.

Plays, Pleasant and Unpleasant. By BERNARD SHAW. London: Grant Richards. In two vols. Price 5*s.* each. 1898.—If any of our readers should wonder why we have taken to reviewing plays he should remember that the drama and the priesthood—or rather we should say the Church, using the term in its widest sense—were formerly very intimately connected; a play in ancient Greece, for instance, was a really religious function. Everyone knows, too, that the callings of medicine and the priesthood were frequently discharged by the same persons. Obviously, then, the connexion between the drama and medicine is clear. The play with which we are more concerned in the present collection is one placed by Mr. Shaw in the "unpleasant" section, and rightly, too, we think—not because it scoffs at sundry medical theories or because Mr. Shaw's presentment of a medical man is a caricature, but on account of its subject, namely, ill-assorted marriages. However, they are matters only too common and their examination is, like a post-mortem examination, unpleasant in some ways but interesting, and if properly undertaken of value in pointing the way to avoid them, or lessen the pathological conditions found, for the future. Dr. P—— has discovered a disease, and this is how he and it are introduced:—

Sylvia. We found that out at home when our great sorrow came.

Charteris. What was that?

Sylvia. I mean when we learned that poor papa had P——'s disease.

Charteris. P——'s disease! Why, what's the matter with P——?

Sylvia. Oh, not a disease that he suffers from, but one that he discovered.

Charteris. The liver business?

Sylvia. Yes; that's what made P——'s reputation, you know. Papa used to get bad occasionally. ..... The doctor never knew what was wrong with him until Dr. P—— discovered a dreadful little microbe in his liver. ..... P—— discovered them first and now he declares that everybody should be inoculated against them as well as vaccinated. But it was too late to inoculate poor papa. ..... Poor old boy! they cut off his liquor, and he's not allowed to eat meat.

In Act 3 P—— is observed while reading a newspaper suddenly to turn pale and stagger. On being questioned he says he has fatal news. "'My disease ..... the work of my life. Look here ..... if this is true it was all a mistake; there is no such disease.'" P—— is naturally much hurt. "'It's all the fault of the wickedly sentimental laws of this country. I was not able to make experiments enough — only three dogs and a monkey. Think of that, with all Europe full of my professional rivals. ..... And now comes this cursed Italian who has ruined me. He has a Government grant to buy animals with, besides having the run of the largest hospital in Italy.'" P—— and Craven have an argument a little further on about the relative cruelty of the war in the Soudan and vivisection. Craven, the man whom P—— had doomed, argues that that was fair fighting and that he risked his own life. P—— retorts that machine-guns were used against naked spearmen, and he adds, with regard to the question of life, "and I have risked mine, as all doctors do oftener than any soldier." To which Craven replied: "That's true; I didn't think of that. I beg your pardon, P——; I'll never say another word against your profession." It is sometimes a little difficult to know when Mr. Shaw is serious, but there can be no doubt about the righteousness of his indignation with slum-owners and sundry other classes in our modern civilisation. All the "Unpleasant" plays are worth reading and so are the first three of the "Pleasant." As Mr. Bernard Shaw has unfortunately selected a name which is similar to the name of a medical man practising in London we have thought it better to use only the initial.

Analytical Records
FROM
THE LANCET LABORATORY.

(1) LIQUID CONFECTION OF SENNA; (2) CREAM DENTIFRICE.

(W. H. LOWE AND CO., 8, STAFFORD-STREET, OLD BOND-STREET, W.)

THE advantages of a liquid confection of senna are obvious. In the preparation of the confection submitted to us the liquid extract is employed instead of the powdered senna leaves, as by this recourse the griping principle of the leaves is eliminated. The preparation, though viscous, is not inconveniently sticky and solid. It is highly aromatic and pleasant to the taste. The cream dentifrice is enclosed in a collapsable tube, and in addition to the presence of approved antacids contains also the extract of quillaia, which has a very pleasant detergent effect upon the teeth and gums. The dentifrice further contains an agreeable antiseptic and essential oils.

SPANISH WINES AND BRANDY.

P. DE OTADUY AND CO., 20, HIGH HOLBORN, W.C.)

We have examined the various specimens of wine sent to us by the above wine-growers with satisfactory results. The character of each specimen may be judged from the following analytical results:—Tudela claret (vintage 1893): alcohol, by weight 8·64 per cent., by volume 10·73 per cent., equal to proof spirit 18·81 per cent.; extractives, 2·08 per cent.; mineral matter, 0·23 per cent.; sugar, 1·04 per cent.; tartaric acid, 0·39 per cent.; and acetic acid, 0·17 per cent. This is a wine of light character and is in sound condition. There is no doubt of its purity. Superior Rioja claret: alcohol, by weight 9·36 per cent., by volume 11·61 per cent., equal to proof spirit 20·35 per cent.; extractives, 2·16 per cent.; mineral matter, 0·26 per cent.; sugar, 1·26 per cent.; tartaric acid, 0·49 per cent.; and acetic acid, 0·16 per cent. This wine is from the vintage of 1892. It possesses slightly more body than the previous wine and its alcoholic strength is slightly higher. It is a sound wine and evidences good bouquet and taste. Royal claret (vintage 1893): alcohol, by weight 10·08 per cent., by volume 12·49 per cent., equal to proof spirit 21·89 per cent.; extractives, 2·23 per cent.; mineral matter, 0·20 per cent.; sugar, 1·70 per cent.; tartaric acid, 0·57 per cent.; and acetic acid, 0·16 per cent. This wine possesses good flavour, but is not so delicate as the previous one. The alcohol is in slightly increased proportion, as are also the sugar and extractives. Sauterne Espagnol (vintage 1891): alcohol, by weight 10·08 per cent., by volume 12·49 per cent., equal to proof spirit 21·89 per cent.; extractives, 1·52 per cent.; mineral matter, 0·18 per cent.; sugar, 0·34 per cent.; tartaric acid, 0·60 per cent.; and acetic acid, 0·24 per cent. This is a white wine of pleasant "dry" character. Its alcoholic strength is precisely the same as that of the previous specimen, but the amount of sugar is quite small. It possesses a peculiar but pleasant flavour and the bouquet is that of a sound wine. Lastly, we have examined the brandy (Toison de Oro), which gives evidence both on taste and analysis of a genuine grape spirit. The results of analysis were as follows: alcohol, by weight 36·28 per cent., by volume 43·26 per cent., equal to proof spirit 75·80 per cent.; extractives, 1·30 per cent.; mineral matter, 0·03 per cent.; acidity equal to acetic acid, 0·054 per cent.; and alcohol derived from volatile ethers, 0·7

per litre. Such a spirit is much to be preferred for medicinal purposes to spirit obtained in a large measure from cereals, since the former contains the ethers of pure wine whence it is distilled. Our examination of these wines afforded no evidence of any sophistication and supports the statement that they are genuine and pure.

VIBRONA CHAMPAGNE.

(FLETCHER, FLETCHER, AND CO., HOLLOWAY, N.)

The analysis of this wine was as follows: alcohol, by weight 10·08 per cent., by volume 12·49 per cent., equal to proof spirit 21·89 per cent.; total solid matter, 1·81 per cent.; mineral matter, 0·13 per cent.; sugar, 0·13 per cent.; fixed acids calculated as tartaric acid, 0·87 per cent.; and volatile acids calculated as acetic acid, 0·0072 per cent. We have not examined a champagne presenting less sugar than is here shown. It is the smallest amount we have ever found in sparkling wines and is practically a negligible quantity. To the palate the wine is exceedingly "dry," just a suspicion only of an added bitter being evident. The wine contains 5 grains of standardised cinchona bark in the form of neutral hydrobromate. This addition in no wise spoils the delicate character of the wine itself, but on the contrary has rather a pleasant effect on the palate. The wine was in perfectly sound condition and possessed, as the analysis also shows, practically no volatile acidity as represented in acetic acid. The sample submitted to us yielded on suitable treatment with solvents the principles of cinchona bark, which occurring in the form of neutral hydrobromate are well tolerated and without the unpleasant effect known as "cinchonism." The wine has a pleasing, delicate, vinous flavour. Its tonic value will be readily conceded from the results of our analysis.

KRONTHAL WATER.

(THE KRONTHAL COMPANY, LIMITED, 66, ST. JAMES'S-STREET, S.W.)

Kronthal Water is derived from the Kronthal springs in the Taunus district, Germany. The waters of the several springs are not identical in composition and character. Thus the degree and kind of "mineralisation" vary. One spring yields an alkaline saline water rich in saline matters, another a similar water but less saline, another an iron water, and another a pure effervescing water which is practically free from common salt. All the waters are now imported into this country in bottles, each being distinguished by a differently coloured label. No salt is added at any step of the bottling process. We have examined samples submitted to us, the first of which was marked with a blue and the second with a red label. The analysis of the sample labelled blue was as follows: total mineral matter 260·40 grains per gallon consisting of 189 grains of sodium chloride, 57·40 grains of calcium carbonate, and 14·00 grains of sodium carbonate. A pint of this water possesses an acid corrective power equal to 14 grains of bicarbonate of soda. The sample of water labelled red has a richer mineral value. The results of analysis were as follows: total mineral matter 327·6 grains per gallon, consisting of 266 grains of sodium chloride, 52·5 grains of calcium carbonate, and 9·1 grains of sodium carbonate. Its acid corrective power is equivalent to 12·5 grains of bicarbonate of soda per pint. Both waters possessed the pleasant soft and delicately saline characters of natural mineral water impregnated with its own natural carbonic acid gas. The waters are of decided merit since they are quite free, as we have found, from any kind of organic impurity and their composition is well adapted to dietetic requirements, especially as diluents on the table. The addition of salt to natural mineral waters containing only a small proportion naturally is a very common recourse, which, however, is unnecessary and superfluous in the present instances. This is a point considerably in favour of waters intended for table use since greater purity is guaranteed by the omission of artificial additions. Our analysis established the purity of these waters.

HOOKER'S MILK WINE.

(THE MILK WINE CO., LIMITED, 9, ARUNDEL-STREET, STRAND, W.C.)

The preparation of this wine is based upon correct physiological principles. In it are contained the peptones derived from the careful digestion of the proteids of milk. According to our analysis the quantity of peptones was equivalent to 9 grains (dry) peptone in one fluid ounce. Further results of analysis were as follows: alcohol, by weight 15·67 per cent., by volume 19·28 per cent., equal to proof spirit 33·79 per cent.; total solid matters, 11·72 per cent.; and mineral matters, 0·78 per cent. In regard to the total solid matter and the amount of mineral matter the wine contains the same proportion as milk. The wine has a sherry-like flavour and possesses "body." It is therefore an agreeable stimulant, modified in the very important respect that it contains a notable amount of well-known nutritive and quickly assimilated substances.

"REFINED SPARKLING GELATINE."

(J. AND G. COX, GORGIE MILLS, EDINBURGH.)

This gelatine yields a clear, excellent jelly when dissolved in hot water and cooled. It is perfectly neutral to the taste and to test-paper. It yields on incineration a white ash which is free from borax and chlorides; the residue, in fact, consists principally of phosphate of lime. The foregoing results afford distinct evidence of the purity of the product. It is therefore well adapted for culinary purposes.

OPMUS BREAD AND BISCUITS.

(JOHN THOMPSON AND SON, SKIRBECK ROLLER MILLS, BOSTON, LINCOLNSHIRE.)

The method of preparation of these foods is particularly directed towards obtaining the highest possible dietetic value afforded by the wheat berry. Accordingly, the proportion of nitrogenous constituents is satisfactory while a maximum proportion of the valuable mineral constituents such as the phosphates is retained. The bread proved to contain 47·73 per cent. of moisture, 6·30 per cent. of albuminoids, and nearly 1 per cent. of mineral matter. The mineral matter contained an abundance of potassium phosphate. In the dried bread the nitrogenous matter would be equivalent to 12·05 per cent. The biscuits presented a similar proximate composition, except, of course, that they contain less moisture and an increased proportion of soluble carbohydrates. The mineral matter amounted to 1·63 per cent. The flavour is very good and the microscope showed the absence of irritating branny particles. The food value of these biscuits is apparent not only on account of the retention of the nourishing constituents of wheat, but because also milk and eggs are used in their preparation.

New Inventions.

THE HOLOPHANE GLOBE.

THE most agreeable as it is the healthiest light is diffused light whether it be from an artificial or natural source. The impact of a direct ray of light upon the eye leads to injurious results in consequence of the constant efforts of the muscles of accommodation of the eye to ward off harmful excess. In spite of the importance of this matter very little regard appears in general to be paid to the kind and character of the light employed for artificial illumination. Commonly a very great excess of light is used and it is concentrated or focussed just upon the area which it is desired to illuminate. Such is invariably the case where writing and reading are concerned. This is true of all classes of illumination, be it electricity, gas, or oil. Even when the eyes are shaded or in the shadows the light reflected upwards is strong and very trying. The Holophane globe is constructed to remove

the ordinary defects of most methods of spreading light. It scatters the light uniformly in any required direction and the absorption during transmission is small. With most globes the absorption of light is enormous, varying from 10 per cent. in the case of clear glass to 74 per cent. in the case of painted opal. The construction and action of the Holophane globe will readily appear from the accompanying diagram. Fig. 1 is a cross section showing the inside ribbing and the manner of diffusing the light. Fig. 2 is a vertical section showing the outside ribbing directing the rays. The illuminated globe has a beautiful and soft appearance. Fig. 3 is a sketch of one particular form, but the principle is applied to all shapes and sizes suitable for electric light, gas, or oil. Although it scatters the rays uniformly in all directions, a very high proportion being transmitted, yet there is nothing that is harsh in its effects upon the eye. There are no sharp shadows. The globe may be looked upon without that sense of discomfort experienced when ordinary opal globes or ground-glass globes are similarly viewed. In regard to efficiency the following may be quoted: A 50-candle power Welsbach light covered with a Holophane globe gives in all directions, from the horizontal to the foot of the light, an average increase of 29 per cent. more light than the bare light, 43 per cent. more light than a clear glass globe, 84 per cent. more light than a ground-glass globe, 169 per cent. more light than an opal glass globe, and 193 per cent. more light than a ground-opal glass globe. According to our experience the Holophane globe gives decidedly the best results with the Welsbach mantle. It affords a distinct economy, since so efficiently yet comfortably is the light distributed as to require a reduced number of burners in a given space. For the electric filament it is not, we venture to think, so well adapted, owing doubtless in this case to the source of light being an incandescent loop instead of a continuous luminous area. For this purpose, however, the spherical globe is the best. With oil lamps the Holophane globe gives excellent results, the illumination being remarkably high, uniform, and subdued in tone. As will be seen, the globe is constructed on well-known optical principles. The globe in reality consists of a series of tiny prisms which gather up and distribute the rays of light in the way they should go, like diffused sunlight, and in accordance with hygienic requirements. The result is a good and uniformly diffused light, healthy, and satisfactory in character. An excellent installation of the Holophane globe may be seen at the show-rooms and offices of the Holophane Company, 91, 93, and 95, Queen Victoria-street, E.C.

FIG. 1.

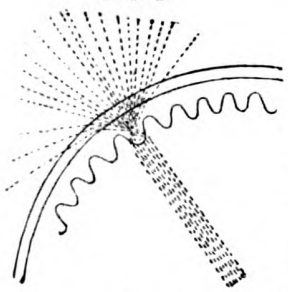

FIG. 2.

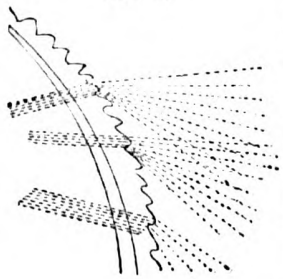

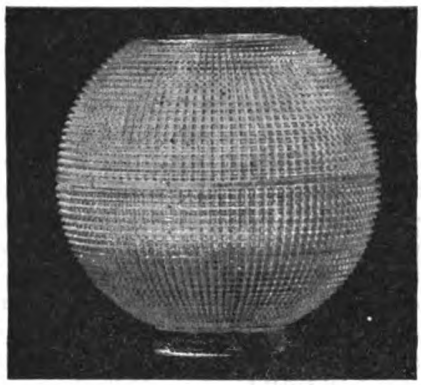

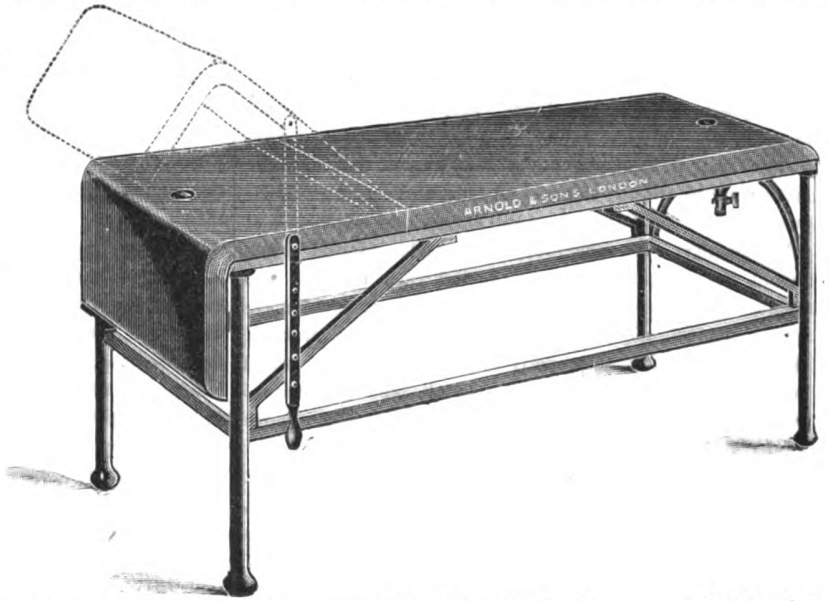

FIG. 3.

A NEW OPERATION TABLE.

LOWERING of the bodily temperature, either from shock or loss of blood or other causes, is often a serious complication in cases of injury and requires to be counteracted by the direct external application of heat, usually in the form of tins or indiarubber bags containing hot water. In the prolonged surgical operations which sometimes have to be undertaken and which are not unfrequently attended by an alarming amount of collapse it is also desirable to ensure a proper degree of warmth as one of the requisites for maintaining the patient's strength. For these reasons it is unquestionably an advantage to have in the operating theatre a convenient reservoir of heat possessing an ample extent of surface, which is constantly in contact with the patient without in any way impeding either examination or operative procedures. With a view to fulfil these various requirements Messrs. Arnold and Sons of West Smithfield have made a new form of operation table, to which they give the name of the Reliance operation table. Its general appearance is shown in the accompanying illustration. It is constructed of iron, enamelled white, and the top, which is also enamelled white, is made double for the purpose of holding hot water. The material of this double top is zinc, and in order to make it capable of carrying any weight with safety it is strengthened internally by a number of arches. This is said to be the first table ever made whereon the patient can be placed in the Trendelenburg position without loss of heat, for the principles of its construction are such that at whatever angle the top may be placed the water remains in the position required.

THE LANCET.

LONDON: SATURDAY, APRIL 30, 1898.

HE is a wise man who is willing to learn even from his enemies, and in the second reading debate on the Vaccination Bill one criticism by an opponent of the measure is worthy the attention both of Mr. CHAPLIN and of the Medical Department of the Local Government Board. Mr. PICKERSGILL in a vigorous and telling speech—curiously different from the utterances of Mr. BAYLEY, the Parliamentary leader of the Anti-Vaccination League and from the oratory of Mr. STEADMAN—prophesied that in a few years glycerinated calf lymph would be discredited, and at the same time he pointed out that the Bill gives no hint of what is meant by the glycerination of calf lymph. If his prophecy is in the very slightest degree to become true it will do so through the neglect to pay sufficient heed to his criticism. With regard to calf lymph glycerine is only a means to an end. The end desired is the practical sterilisation of the lymph excepting as regards the vaccine itself. A mixture of a little glycerine with a little calf lymph by any druggist's apprentice might be advertised and sold as "glycerinated calf lymph," yet it might be any distance removed from "aseptic calf lymph." Dr. MONCKTON COPEMAN and those who have intelligently followed his methods or pursued similar methods have found asepticism by glycerine to be an attainable goal; but who shall say that within the next few years the market may not be flooded by compounds of glycerine and lymph no better than that unfortunate sample the use of which at Rügen some years ago was followed by a troublesome skin eruption, and the well-merited denunciation of which by the late Sir GEORGE BUCHANAN has recently proved a perfect godsend to anti-vaccinationists everywhere. We believe that glycerinated calf lymph has a splendid future of usefulness before it if that future be properly guided and safeguarded, but it is of the utmost importance that no initial laxity shall be allowed to breed mistrust and confusion in the public mind. The Vaccination Bill should take cognisance of this difficulty. All who profess to provide aseptic lymph should be registered or licensed, and their methods and results should be subject to whatever governmental inspection or control may be necessary for the general welfare. We cannot think that properly regulated inspection would be anything less than welcome to all reputable makers who are primarily interested. No doubt another course would be to prohibit the use of any lymph excepting that supplied by Government, but that would raise questions of compensation which Mr. CHAPLIN might not care to face, and it might exercise a deterrent influence as regards original research.

Excepting in one or two points on which he exhibited too uncompromising an attitude Mr. CHAPLIN made a statesmanlike contribution to the debate and showed a very full grasp both of principle and of detail. He seems prepared to agree to the introduction of clauses providing both for the primary vaccination of children entering school, where the operation has not previously been performed, and for the revaccination of children about to leave schoo These additions to the Bill would be of very great value towards the prevention of small-pox. Having indicated his willingness to go so far Mr. CHAPLIN might make up his mind to go even further with regard to two points, one of which would do much to conciliate the medical profession, while the other would do much to conciliate the opponents of compulsion. In THE LANCET of April 16th we stated a case for acceptance of the vaccination work of private practitioners as work done for the State, subject to its fulfilling State requirements. Though no really valid objection has been raised to this proposal it has not yet been accepted by Government. When the adjourned debate is resumed we trust that Mr. CHAPLIN will have seen his way to add this to his scheme. The other point is as to the recognition of declarations of conscientious objection. One very momentous statement which Mr. CHAPLIN made in the course of his speech gives to this question even greater importance than before. But it is necessary to be quite clear here as to what is meant by abolition of penalties. No one would be fined for refusal of vaccination. There would still, however, be fines for refusal alike of vaccination and of the alternative provided for vaccination—namely, the visit to a magistrate or a law court for the purpose of making a declaration of conscientious objection and the subsequent registration of a declaration so made. Under any circumstances, therefore, prosecutions would still require to be provided for. Now, Mr. CHAPLIN announced that in future and altogether independently of the present Bill all prosecutions which may be required under the Vaccination Acts are likely to be conducted by the vaccination officer even in places where boards of guardians are hotly opposed to prosecutions. The officer will prosecute by order of the Local Government Board. In principle we entirely agree with this proposal. It will at once abolish the anomalous conditions at present prevailing by which a man living on one side of a hedge may go scot-free as regards infringement of the law while a man on the other side of the hedge will involve himself in prosecution and penalty for similar infringement. But in practice this proposal may do far more harm than good if it be too rigorously enforced in places where anti-vaccination has been long established. What we suggest is that if prosecutions are to be carried out independently of local authorities a conscience clause should be introduced, and prosecution should take place only where a statutory time for taking advantage of the conscience clause has been allowed to elapse without the necessary declaration having been made. We would not for a moment propose that, a prosecution under such circumstances having once been raised, the defaulting parent should still have this way of escape open to him. Any such extreme facility would be liable to systematic abuse under the guidance of anti-vaccination societies. But if prosecutions are to be instituted all over the country by officials acting independently of local authorities they should

be limited as above indicated, and Mr. CHAPLIN should have all the less hesitation in agreeing to this, looking to the discovery which he has made of the powers existing under the present law. Further, under such a scheme he need no longer have any hesitation in substituting sanitary authorities for Poor-law authorities to carry out all the rest of the local administration of vaccination.

In what we say here we are endeavouring to consider the question as a whole. There would be under the new system the use of aseptic calf lymph; the extension to six or twelve months of the age limit for primary vaccination; domiciliary vaccination; State payment of efficient vaccinations by private practitioners; the recognition of conscientious objection; prosecution independently of local option for neglect to register conscientious objection within a statutory period; the inspection of children beginning school attendance, with the offer of primary vaccination where not previously performed, but again subject to a conscience clause; and revaccination at adolescence, similarly subject to a conscience clause. It seems to us that all this hangs together as a workable scheme, and that the omission of any one part would weaken the whole and make it less likely to be successful in accomplishing the desire alike of the President of the Local Government Board and of the medical profession—namely, that there shall be in this country such approach to a maximum of vaccination and revaccination as may be consistent with a reasonable minimum of friction and opposition.

THE extremely lucid and interesting speech with which the Chancellor of the Exchequer introduced his Budget proposals and the proposals themselves are matters of high interest to all intelligent citizens and not least so to members of our own profession. The mere growth of wealth is a matter of great importance to all classes and especially so to a profession which concerns itself with the physique of the race and is responsible for its health and in some degree for its morals. We are constantly hearing of poverty and competition and the struggle for life, and yet one Chancellor of the Exchequer follows another declaring the ever-increasing scale of the public income, rising to the demand for an ever-increasing expenditure of the public money. The most liberal estimate of the yield of a tax in one year is found to be exceeded by its actual results in the year following; and a surplus of two or three millions has to be disposed of with so slight a clamour for a share of it as to give the Chancellor little help in his delicate task. A generation ago a penny in the income tax used to yield £1,000,000, now it yields £2,150,000. Fortunately men do not necessarily decay when wealth accumulates. It is quite possible to have the opposite result, and we are fain to believe that with all the increase of wealth and even luxury among us there is still no serious deterioration of the national morals or the national health. Drunkenness and the coarser forms of vice, though still far too common, are less so than in former generations. Stimulants are still in demand both for mind and body, but they are of a healthier kind than formerly. Open air, exercise and motion in the open air, travelling, reading, painting, music, all enter into the conception of modern life in a way tha renders it altogether different from the humdrum existence of a few generations back. We are no longer the deepest drinkers of alcohol in Europe. France heads the list now and exceeds us, as do Denmark, Belgium, Switzerland, and Germany. It is to be admitted that our rulers have done much to add to the cost of indulgence in alcohol, and by so much may claim some of the credit of our greater sobriety. But we still drink prodigiously, and in this excess gratify each successive Chancellor by vast contributions to the exchequer representing quantities of alcohol beyond all physiological need of the human body and tending as powerfully to the degradation of morals as to the degeneration of the tissues. In the year which has just closed the exchequer was benefited by an increase of Excise duties over those of the previous year of £840,000, the principal increase being for beer, which amounted to nearly half a million of money.

The Chancellor's present Budget will be remembered in history as the Budget which diminished the tax on tobacco. He had a surplus of £1,786,000, nearly enough to have abolished half the present duty on tea. He cast about for recipients for his favours and he has chosen, first and chiefly, the consumers of tobacco. To this section of the community, excluding nearly all its women and children and a large number of its men, he has given an almost unasked grant of £1,120,000. He has done this with the deliberate hope of not diminishing his own receipts by largely stimulating the public demand for the article which he so favours and which is not one the consumption of which either needs or deserves stimulation. We doubt if this desire will have fulfilment, for the reduction in price on a small quantity will be infinitesimal and will very likely benefit the consumer who buys tobacco by the ounce little more than the doing away with the coal dues benefited the buyers of half sacks of coal. A sermon from us on this action of the Chancellor of the Exchequer would be as ineffective as the one he so pathetically described as preached to the House of Commons by himself on the need for economy, "which produced no more effect than if it had been preached in church." Medical men, whatever their views of tobacco, use it almost as freely as other classes of the community, and although it is a luxury it has arrived at being almost a necessity. In conditions of poverty the "weed" seems to have a charm which exceeds that of actual necessaries—doubtless because it lessens the sense of want. It is pathetic to see the pauper out for the day pick up from the street the refuse end of the cigar that has been thrown down by his more wealthy neighbour. All this may be admitted, and yet some will think that there is enough tobacco consumed already, and that when Sir MICHAEL HICKS-BEACH was casting about for a use for his surplus he might have found a worthier object than the one he has chosen. On the rival merits of tea and chocolate we shall not dogmatise. Both are undoubted boons, and the increased consumption of them would favour the greater sobriety of the country in a way that the increased use of tobacco is scarcely likely to do.

Though we are not inspired with admiration for the chief remission of the Chancellor's Budget we must express our gratitude to him for the small but considerate reductions in

the Income Tax on incomes varying from £400 to £700. We feel that we are being thankful for small mercies, but in the absence of larger ones this is the only exercise for our gratitude. The incomes included in this remission will, we fear, include a large proportion of medical incomes very laboriously and dearly procured, as well as others, and we cannot but regret that the surplus was not used more freely in this way. The turn of the payers of direct taxes must come soon. Meantime it is gratifying to think that they have not been altogether overlooked.

THE governors of the Belgrave Hospital for Children have resolved on an experiment in the administration of their charity which will have the goodwill of all intelligent philanthropists in the metropolis and of the medical profession generally. They have decided to transfer the hospital from Pimlico to a site in Kennington adjoining St. Mark's Church in the Clapham-road. But they have done much more than this—they have determined in the populous locality in which their future operations are to be carried on to try at least to conduct them in accordance with sound principles of charity. His Grace the Duke of WESTMINSTER is the president of the hospital and in a letter to the *Times* of April 23rd he sets forth the views of the governors in a way which ought to secure a sympathetic and substantial response from the public and especially from those in the South of London who can afford to be charitable. A fuller statement of the scheme for the reconstitution of the Belgrave Hospital for Children in South London is before us, of which the principal features may be thus summarised. The general administration of the hospital will be in the hands of the committee of management which will also appoint the medical staff. The Committee will include the physicians and surgeons and three other members of the staff. It is well known that the provision for hospital treatment of the sick poor in the south of London is very inferior to that in other parts and this attempt to redress the grievance deserves every encouragement. According to the Duke of WESTMINSTER'S letter the people of the north side of the Thames have nearly four times as much hospital accommodation for their children as those living on the south side of the river.

But it is principally on account of the determination of the governors to face manfully the question of hospital abuse that we commend this hospital to the support of all liberal men. In the admission of both in-patients and out-patients a serious effort will be made to include only those classes who really need hospital accommodation. A wage-limit scale has been drawn up, but in cases of long illness or of a serious operation it will not be pressed if a recommendation is forthcoming from a medical practitioner that the patient is deserving of charitable treatment. Much stress will be laid in all cases on the recommendation of medical men. Both they and the representatives of charitable institutions will be invited to coöperate with the governors in preventing the abuse of the hospital. Coöperation with medical men—not competition—will be the key-note of administration. And where a medical man has a patient whose case is obscure or difficult and the parents are too poor to pay a consultant's fee, it is proposed that he may send or take his patient to the hospital and there have a consultation with one of the staff. This is a much-needed arrangement in every part of London and the provinces. The patient would by it secure the advantage of a hospital opinion and yet his self-respect and his connexion with his regular medical man would be left intact. It is intended to restrict the number of new out-patients seen in a day, preference being given (1) to those most seriously ill, (2) to those sent by medical practitioners, and (3) to those bringing certificates from governors. Great precautions will be taken to prevent the out-patient department being a medium for the diffusion of infectious disease, a special waiting-room being provided for suspicious cases. In the case of the in-patients, too, special precautions will be taken by means of a "resting ward" and isolation wards to minimise as far as may be the risk of infection spreading. Another feature of the new administration is to provide a training for nursemaids, such as will supply that important class of servants with some knowledge of the proper methods of rearing infants and nursing them when they are ill. Very properly it is intended to reserve some privileges for the Pimlico district in which many of the supporters of the hospital reside. We venture to hope that a hospital so much needed and to be conducted on principles so sound will soon get the £50,000 which the Duke of WESTMINSTER says will be necessary to carry the scheme into effect.

Annotations.

"Ne quid nimis."

SOLDIERS' BOOTS.

MR. G. W. STEEVENS, the Soudan War Correspondent of the *Daily Mail*, gives a lamentable account of our soldiers' footgear. In a recent letter he says: "What might have been avoided, and should have been, was the scandal that the men's boots gave out. ..... When the three battalions and a battery arrived in Berber hundreds of men were all but barefoot; the soles peeled off, and instead of a solid double sole revealed a layer of shoddy packing, sandwiched between two thin layers of leather." It is true, Mr. Steevens goes on to say, that the Soudan climate is particularly destructive of all things stitched and that the soldiers had done a great deal of marching, but, on the other hand, they had only been "up river" about a month, "and no military boot ought to wear out in a month." The footgear of a marching army is unquestionably the most important part of the whole equipment, and yet whenever our troops are engaged on active service there are pretty sure to be complaints more or less bitter regarding its quality and durability. The Egyptian soldiers wear a riveted boot which apparently is able to withstand the climate as well as the long marches across the desert. If this is correct it is strange, to say the least of it, that the experience thus ready to hand was not utilised for the benefit of our infantry when they were ordered to the front. It is poor economy to grudge a little extra expenditure on soldiers' footgear, especially when the men are about to proceed into regions where transport is the chief difficulty. "Boots are always the most pressing need on a campaign," said the great Napoleon in a letter to Prince Eugène de Beauharnais, and in order as far as possible to guard against a deficiency the prescient commander ordered the provision of eight pairs of boots for

each foot soldier. Napoleon's famous rival was likewise deeply anxious that his men should be well shod. "What is the most essential thing for a soldier?" asked a member of the Government of the Duke of Wellington. "A good pair of boots to begin with," replied the hero of Waterloo; "and in the next place a second pair of boots; and thirdly, a spare pair of soles." Alexander's victorious army reached India on sandals and to this day a similar flimsy foot-protector is generally worn in eastern countries, but the ideal boot for a modern soldier should be impervious to moisture, stout and yet pliable, accurately shaped, and constructed of the most durable material. It should also be easily put on and taken off, should prevent the entrance of dust, sand, or mud, and, above all, favour the free play of each pedal articulation, while at the same time affording support to the muscles of the foot and ankle collectively. An ill-fitting, clumsily shaped boot is worse than none at all. Undue pressure or friction at any point quickly leads to corns and lameness. Formerly bunions and in-growing toenails due to pointed boots and shoes were common causes of a halting gait amongst the population generally, but of late years more attention has been given to the anatomical features of the foot, especially in growing children. Deformed feet are, however, still of frequent occurrence in the ranks, each case demanding special treatment; but it should be an invariable axiom with officers commanding companies that boots should be made to fit the feet and not *vice versâ*. The following recipe for making boots both soft and waterproof was recommended by Edmond Parkes, and amongst *laudatores temporis acti*, at all events, it still holds first place: "Take half a pound of shoemakers' dubbing, half a pint of linseed oil, half a pint of solution of india-rubber; melt together with care and rub in firmly." The indiarubber solution is highly inflammable, requiring attention during the melting process. Mr. Steevens's concluding remarks are noteworthy: "It is always the same story—knavery and slackness clogging and strangling the best efforts of the British soldier. To save somebody a few pence on a boot you stand to lose a good rifle and bayonet in a decisive battle and to break a good man's heart into the bargain. Is it worth it? But it is always happening; the history of the army is a string of such disgraces; and each time we arise and bawl 'Somebody ought to be hanged.' So says everybody. And nobody ever is hanged." In answer to a question asked in the House of Commons on April 19th Mr. Powell Williams said that the boots supplied to the army in Egypt were not shoddy but made of the best English hide. Between the inner and the outer sole strips of leather were inserted to give elasticity. The *Times* of April 26th contains a letter from its special correspondent, dated Atbara, April 11th. He says that the most searching inquiry should be made, that the soles came away from the uppers, and this after six weeks' wear. Perhaps Mr. Powell Williams will make inquiries.

A TIMELY PUBLICATION.

THOSE who have read the Final Report of the Royal Commission on Vaccination, together with the appended statement of the two dissentient members of the Commission (Dr. Collins and Mr. Picton), will, it may be hoped, also peruse the very exhaustive and convincing criticism of the latter made by Dr. J. C. McVail in a paper, read before the Epidemiological Society of London, which has just been separately published.[1] It may be recalled that the conclusion arrived at by the "dissentients" was that there was insufficient ground for the compulsory enforcement of vaccination and they recommended the repeal of the compulsory clauses of the Vaccination Acts without, however, interfering with the rest of the machinery which would permit those desirous of being vaccinated to be vaccinated; in other words, that vaccination should be voluntary but that the State should still maintain its establishments and encourage if it did not enforce the performance of vaccination. The route whereby such conclusion is reached traverses the whole of the ground covered by the Commission—historical, statistical, and theoretical, and step by step Dr. McVail follows the two Commissioners' statements, showing where fallacies have crept in and where errors of judgment have been committed. The publication is a timely one in view of the action of the Legislature, for, although ostensibly a "review," the *brochure* enables the reader to glean much information upon the whole subject, and we can heartily commend it as a brilliant exposition and able criticism of the most powerful plea against general vaccination which has been, and which probably can be, advanced.

[1] The Report of the Royal Commission on Vaccination: A Review of the Dissentients' Statement. By John C. McVail, M.D. London: P. S. King and Son. Price 2s.

DEATH OF SIR VIVIAN MAJENDIE.

BY the sudden death of Sir Vivian Majendie at Oxford last Sunday the Government and the country have lost a valuable adviser and expert. No one was more familiar with the distinctive properties of the great number of explosives now in existence than Colonel Majendie and his plucky investigations were invariably carried to an instructive issue without personal harm. We have frequently had occasion in these columns to refer to his work on matters concerning the public safety and quite recently we drew attention to the important conclusions to which he had come on the petroleum lamps accidents question, conclusions which were in entire agreement with those arrived at by THE LANCET Analytical and Sanitary Commission on Dangerous Paraffin Lamps, the report of which appeared in this journal on Jan. 4th, 1896. Only last week he gave evidence before the Select Committee and was cross-examined as to the objections he entertained against raising the flash point of illuminating oil. This cross-examination was not concluded, and the Select Committee must deeply regret having lost one who was probably their most valuable witness. The public will remember Colonel Majendie as the Chief Inspector of Explosives to the Home Office, whose business it was to deal with the explosions which occurred on the Underground Railway, at public offices, and elsewhere, and with those dastardly outrages which are now and again committed by mad and miscreant individuals.

THE EARLY DIAGNOSIS OF MEASLES.

HE would be a great benefactor who would discover a sure sign or symptom of measles at an early stage of the disease. The *New York Medical Record* of April 9th has an original article by Dr. Henry Klopik, attending physician of the Good Samaritan Dispensary, New York, on a New Diagnostic Sign of Measles. This physician thinks that he has discovered an unfailing and pathognomonic indication of the disease which is to be seen two or three days before the appearance of the eruption. The epidemic which rages amongst us just now will enable our readers to verify or otherwise the interesting observation of Dr. Klopik. The sign is to be found in the mouth—*limited to the mucous membrane lining the cheeks and lips*—and is thus described by him: "It consists of small, irregular spots of bright red colour; in the centre of each spot is the interesting sign to which I call attention. In strong daylight we see a most minute bluish-white speck. These minute bluish-white specks in the centre of a reddish

spot are absolutely pathognomonic of being measles. I have never met them elsewhere and when once seen they are a certain forerunner of the skin exanthema." The spots are not to be confounded with the red spots seen on the palate and fauces commonly enough in measles. Dr. Klopik says that the observation of these spots by himself and friends has been useful in the way of early separation of cases and limitation of the spread of the disease. But even if his account be confirmed the spots do not occur in most cases till within one, two, or three days of the eruption, when probably the infection has been communicated to others. The eruption is really generally anticipated for several days by well-known symptoms, such as cough, sneezing, red eyes, pyrexia, &c. Still, every minute clinical observation is valuable and tends to the perfection of medical science and service.

THE BLOEMFONTEIN COTTAGE HOSPITAL.

ON April 4th Sir Alfred Milner, the Governor of Cape Colony, opened the Victoria wing of the St. George's Cottage Hospital, Bloemfontein. The original hospital consisted of a general ward of four beds, two private wards, a convalescent room, dispensary, dining-room, sister's and nurses' room, a kitchen, and offices. Last year the sum of £1800 was collected in honour of the Diamond Jubilee—a large sum for a little up-country town. Of this £1200 were handed over to the hospital, £400 were used to pay off a mortgage, and £800 were expended on the new wing, which comprises two nurses' rooms, a general ward of four beds, one private ward, and a linen cupboard. The new wing is a great addition to the hospital and the townspeople of Bloemfontein are to be heartily congratulated.

THE THERAPEUTIC AND TOXICOLOGICAL EFFECTS OF CHINOSOL.

AN investigation which throws light upon the properties of any new antiseptic will be welcomed by the members of the medical profession in, it may be, warning them as to its drawbacks whilst also pointing out its advantages. Chinosol is now largely employed as a powerful and convenient antiseptic and it is said to possess very distinct advantages over other antiseptic compounds previously in use. It is a yellow powder of definite chemical composition, soluble in water, and containing a quinoline group in combination with potassium and the sulphate radical. Its antiseptic, disinfectant, and deodorant properties have been determined with very satisfactory results by Dr. Klein. It is important next to turn to its properties in practice and on this important question Professor Hobday, F.R.C.V.S., of the Royal Veterinary College, has contributed an interesting and instructive paper to the March number of the *Journal of Comparative Pathology and Therapeutics*. His experiments related to dogs, cats, and donkeys. The internal administration of chinosol to human subjects has been tried by Dr. Cipriani, whose results are recorded in THE LANCET of Nov. 27th, 1897. In this communication the treatment of tuberculosis with chinosol administered by the mouth or injected locally was followed by a rapid and apparently permanent improvement. The summary of Professor Hobday's results is as follows: 1. Chinosol acts well as an antiseptic, disinfectant, and deodorant when used in certain proportions. 2. Its action is better marked when used as a lotion than when used as a powder. 3. The powder is not suitable for use on fresh wounds unless diluted in some way or other. 4. For the disinfection of instruments care must be taken not to make the solution too concentrated. With instruments care must be taken, Professor Hobday finds, that the solution should be of definite strength, as otherwise the instruments lose their edge and the handles become discoloured and rough to the touch. 5. The drug possesses toxic properties. 6. If used subcutaneously in too concentrated a form chinosol will produce local irritation and swelling. The strength recommended for subcutaneous injection in human practice is from 1 in 600 to 1 in 200, and certainly in veterinary patients this should not be exceeded. 7. The cat is very susceptible to its action and in this animal much more care is necessary to guard against toxic symptoms than in the case of the dog. In the cat, if subcutaneously injected, the extreme limit of dose should be one-sixteenth of a grain for each pound body weight and in the dog one-eighth of a grain per pound. 8. Chinosol is not rapidly absorbed from the unbroken skin of the dog and can be applied for several days in succession, even in fairly concentrated solutions, to the skin of this animal without producing eruptions or sores. 9. The chief symptoms of poisoning are: sneezing and coughing and increased flow of thick, ropy saliva; subnormal temperature; staggering gait, commencing with loss of motor power in the hind-quarters; great prostration, and ultimately death from failure of the heart's action. 10. The chief post-mortem characteristic is the smell of chinosol on or in some part of the body, whilst another symptom to be looked for is the presence of frothy saliva in the pharynx, œsophagus, or stomach.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.

AT the annual meeting of the Manchester and Salford Hospital for Skin Diseases held on March 4th the report of the committee for 1897 stated that there had been 3149 new patients, as against 3271 in 1896—a decrease of 122, which was attributed to more careful inquiry into the claims of the applicants for charitable relief. It is well that hospital managers should do their share in checking the abuse of hospitals by well-to-do and shameless people. One point brought out is the great extent to which the hospital—in common with other Manchester charities—is "bled," as Dr. Brooke put it, "by the neighbouring towns, which sent large numbers of patients but whose contributions were almost *nil*." It was said that the mayors of several towns had been written to on the point but that not a single reply had been received. Bolton sent 340 patients, Bury 192, Crewe 163, Northwich 139, Warrington 206, Macclesfield 153, Oldham 226, Rochdale 169, and Stockport 417. It is not quite fair that the places named should draw upon the charities of Manchester for the medical relief which they themselves are well able to afford. As is too commonly the case, "the committee regretted, however, that the expenditure still exceeded the receipts" by nearly £500, and a strong appeal was made for more subscriptions.

ABSENCE OF PYRAMIDAL DECUSSATION.

DR. PHILIP ZENNER of Cincinnati relates in a recent number of the *Neurologisches Centralblatt* the case of a patient who was under his care on account of slight left-sided paralysis. He was a man, aged thirty-three years, a waiter, whose condition was such that no reliable history could be obtained of the onset of his illness. It was found out later, however, that there had been a series of apparently Jacksonian fits affecting the left side about a year before his admission to the hospital. When he was admitted there was a slight dragging of the left foot as he walked, the left hand was weaker than the right, there was left-sided facial weakness, especially in the upper part of the face, but no reaction of degeneration. The tongue was protruded to the left and there was apparently some difficulty in deviation of the eye to that side. There was no impairment of sensibility. Percussion of the skull revealed the fact that there was considerable pain on the

left side and the patient complained of headache over the frontal region and in the left temporal region. Intelligence was impaired and any answers were given very slowly. There was what is called "congestion" of the papilla with widening of the arteries and veins, but no distinct optic neuritis. He remained two months in hospital without changing much. He was stupid, often melancholy, and there was a tendency to somnolence. He died about a month later in an asylum and a tumour was found over the central region situated under the dura mater and apparently compressing but not destroying the convolutions. It was a glio-sarcoma and was situated on the left side of the brain. A careful examination of sections of the medulla and the upper region of the spinal cord by Dr. Kramer revealed the curious fact that there was no decussation of the pyramids, thus accounting for the presence of paralytic symptoms on the left side in a case in which the cerebral lesion was on the same side.

DR. W. G. ROCKWOOD AND THE CEYLON MEDICAL SERVICE.

DR. W. G. ROCKWOOD, who recently retired from the post of colonial surgeon and also that of surgeon to the General Hospital, Colombo, has just been appointed consulting surgeon to the same institution, an office newly created by the Government "for long and distinguished services." Dr. Rockwood, who is a pure Tamil, graduated at the University of Madras and entered the Ceylon Medical School in the same year (1866). He took the degree of M.D. at Madras in 1872 and became M.R.C.P. Lond. and M.R.C.S. Eng. in 1885. For the last twenty years he has been surgeon to the General Hospital, Colombo, and Lecturer on Surgery in the Ceylon Medical College. He has, in addition, just been appointed by his Excellency the Governor to be an unofficial member of the Legislative Council of Ceylon to represent the Tamils. The medical profession will, we are sure, join with us in congratulating Dr. Rockwood upon the honour which he has so worthily attained.

THE CONTROL OF MEASLES AND WHOOPING-COUGH BY SCOTCH SANITARY AUTHORITIES AND SCHOOL BOARDS.

A CORRESPONDENCE of considerable importance and significance in the direction of the prevention of disease has recently passed between the clerk to the Montrose Landward School Board and the Scotch Local Government Board, the question at issue being as to whether measles and whooping-cough are to be held to be infectious diseases within the meaning of the Public Health (Scotland) Act, 1897, even although a sanitary authority may not have added these two diseases to those notifiable under the Notification Act. The necessity for deciding this point arose out of the provisions of Section 57 of the Public Health Act, which, *inter alia*, imposes a penalty upon parents and school teachers who knowingly permit a child to attend school who has been suffering from infectious disease or who has been residing in a school where such disease exists, unless the child in question produces a certificate from a medical officer of health or a medical practitioner stating that he or she is free from infection. The certificate in the case of the medical officer of health has to be provided free of charge. The Scotch Local Government Board have, we are glad to see, no doubt as to the interpretation to be placed upon Section 57 and they have laid it down that its provisions are in no wise limited to the definition of infectious disease contained in the Notification Act. They regard both measles and whooping-cough as dangerous infectious diseases and the school teachers are to have regard to the provisions of section 57 when dealing with these diseases. We welcome this decision as a move in the right direction, though we fear that in times of epidemic measles or whooping-cough the medical officer of health will have a somewhat busy time; doubtless, however, his emoluments will be correspondingly increased. The gradual growth of public opinion in favour of controlling those infectious diseases which hitherto have been allowed to run riot as their natures prompted them is one which will have to be encouraged gently and discreetly by the public health service. Reform lies rather in the direction of educating the public to the necessity for caution than, in the first instance at least, in resorting to injudicious prosecution. If we are to reduce the mortality from such diseases as measles and whooping-cough the exercise of tact on the part of the medical officer of health is of the utmost importance, and it is only by this means that we can gradually educate the public for the more stringent measures which may ultimately have to be taken.

ACUTE PANCREATITIS.

ACUTE pancreatitis is not a very common disease and sudden deaths occurring from this cause always have a pathological interest. The *Hong-Kong Weekly Press* of March 26th contains an account of an inquest held upon the body of Alfred Feltham, the wardmaster of the Government Civil Hospital, who was found dead in his quarters at the hospital on March 17th. Dr. Atkinson, the principal medical officer, in his evidence said that he was summoned in the afternoon to see Mr. Feltham. He found him lying dead on the sofa. At the post-mortem examination made on the following day, at which he was present, the cause of death appeared uncertain and the stomach and contents were handed over to the Government analyst. Mr. Frank Browne, the Government analyst, deposed to examining the contents of the deceased's stomach: it contained 19 gr. of chloral and ¼ gr. of morphia. He had last seen deceased alive at midday on the 17th. Dr. J. A. Lowson, who made the post-mortem examination, deposed to finding acute inflammation of the stomach and pancreas; in the head of the latter there was a large hæmorrhagic extravasation. The condition found could not have been caused by either chloral or morphia and in all probability the deceased could not have taken more than 30 gr. of chloral for the absorbing powers of the stomach must have been considerably impaired. The cause of death was syncope in acute gastritis and pancreatitis possibly accelerated by a medicinal dose of chloral. The presiding magistrate gave his finding in accordance with this evidence.

THE REPEAL OF THE CONTAGIOUS DISEASES ORDINANCE IN SINGAPORE.

IN a paper addressed to the Secretary of State for the Colonies Mr. William Adamson, chairman of the Straits Settlements Association, shows that venereal disease has greatly increased in Singapore since the repeal of the Contagious Diseases Ordinance and he declares it to be the belief of the association that the Ordinance ought to be again put in operation without delay. In the colony the main provisions of the Ordinance were repealed in 1888, leaving only to the Government the right of registration and the inspection of houses of ill-fame, but in 1894 (Women and Girls Protection Ordinance Amendment Bill) this right was withdrawn and since then there has been no inspection or control exercised beyond what is provided for by the common law. The repeal of this Ordinance was in obedience to the course resolved upon in England and under the peremptory orders of the Colonial Office, but it was done against the protests of the Colonial Government, of the non-official members of council, of the naval and military officers, and of the civil and military medical staff. Some results of the repeal are made evident by the fact that during

the five years 1884–88 inclusive, when the Ordinance was in operation, out of an average of 615 English soldiers in the Tanglin Barracks in Singapore the admissions to hospital for primary syphilis, secondary syphilis, and gonorrhœa were 144 per mille, whereas during the last five years, 1892–96 inclusive, which have elapsed since the protective legislation was abolished out of an average of 682 men in barracks the average admissions to hospital for the same diseases were 434 per mille. The admissions to hospital per mille for these diseases during each of the years comprised in the above period were as follows: 123 in 1884, 81 in 1885, 69 in 1886, 161 in 1887, 287 in 1888, 330 in 1892, 265 in 1893, 348 in 1894, 617 in 1895, and 567 in 1896. There is a considerable amount of evidence to the effect that the prostitutes, of whom there are more than 3000 in Singapore, are practically in a state of slavery to the mistresses and that the hardships of their position were mitigated by the enforcement of the Ordinance.

THE LATE SIR RICHARD QUAIN AND THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

As stated in our report of the proceedings of the last Comitia of the Royal College of Physicians of London, the College was enriched by a gift bestowed by the late Sir Richard Quain a few weeks before his death—an act which testifies to the attachment he bore to the College. The gift referred to consists of four pieces of plate, one a handsome silver bowl inset with medals gained by him during his collegiate and university career. The most striking piece is a beautiful candelabra fitted for the electric light which was a gift to Sir Richard Quain from a grateful patient, as also was a silver salver. Another silver salver bears an inscription stating that it was presented to him by the Pathological Society for services rendered to it as honorary secretary. At the time of his death Sir Richard Quain was, we believe, the last of the original members of this Society which celebrated its jubilee in 1896.

ICTERUS GRAVIS.

WE publish this week two most unusual cases. One, a case of acute atrophy of the liver related by Dr. William O'Neill, presents several points of interest apart from the rarity of the disease. Great intensity of pain is not usually experienced in acute atrophy of the liver and the duration — five days — is very short. Dr. O'Neill's comments on his case are well worthy of perusal. He maintains that this condition is a general disease in which all the organs of the body suffer more or less and in all probability micro-organisms of a malignant character are the exciting cause of the malady. This is the view taken by most modern writers. The second case is recorded by Dr. E. O. Daly. He heads his article, "A Case of Icterus Gravis." As is well known, cases of jaundice assuming a malignant course do occur either in endemic or epidemic form. Dr. Hunter, writing in Professor Clifford Allbutt's "System of Medicine" (vol. iv., p. 114), draws attention to the same point, instancing the extensive epidemic outbreak of jaundice which occurred in Saxony and Dresden in the autumn of 1889 when no fewer than 518 persons were attacked. He considers that the evidence of acute yellow atrophy being a rare form of malignant jaundice of obscure infective nature outweighs that in favour of any other theories which have been advanced. Dr. Daly's case was a very acute one, proving fatal in three days. Unfortunately no post-mortem examination was allowed, so that the exact condition of the liver and kidneys could not be determined. The only diagnosis which could be arrived at was icterus gravis and Dr. Daly's arguments in this respect are perfectly sound. We should feel inclined from our perusal of the case as reported to support this diagnosis and to refer its pathogeny to a micro-organism. It is evident that there was a virulent organic poison, probably formed within the intestinal tract, the first symptom being vomiting. There was no diminution in the liver dulness; neither leucin nor tyrosin was found in the urine and subsequently there was complete suppression of urine; all these points, as Dr. Daly remarks, point away from acute yellow atrophy of the liver, so this case differs very materially from the one under the care of Dr. O'Neill. A comparison between the two cases is most valuable and it is fortunate that it was possible to publish them together.

STREET NOISES.

THE municipality of Brighton is making a most laudable effort, and one which we earnestly hope will succeed, to deal with the curse of unnecessary street noises. A proposal was submitted to the town council on April 21st providing for a penalty of £5 being inflicted upon anyone who in offering goods for sale in any public thoroughfare should make "any loud or continuous outcry or noise or importune any person so as to be or to cause a nuisance or annoyance to any of the inhabitants." A similar penalty was proposed to be recoverable from any persons who after being requested to desist from playing any musical or noisy instrument, or singing or shouting in any street within 100 yards of where any persons may be assembled in any place of public worship or public hall or hospital or similar place. This last proposal is, to our thinking, not strong enough. Persons making these abominable noises should be requested to go away and fined if they do not whether there are any persons assembled for public worship or not. Still, however, the action of the Brighton authorities is a long step in the right direction, and we see that the proposal was carried by 35 votes to 11. It will, however, require the sanction of the Local Government Board before becoming operative. The unfortunate people who have to live in London, except the favoured dwellers in Montagu-square, are at the mercy of any lazy loafer who likes to buy a few newspapers or drag an organ about. The London County Council have had the matter "under consideration" for some time and they might at least try to stop the nuisances which we have indicated. There is no possible excuse for the newspaper "runners," for plenty of street newspaper hawkers sell their goods without yelling and make a livelihood thereby.

MEMBRANOUS STOMATITIS.

THE frequency of true diphtheria and other inflammations attended by formation of false membrane in the throat is in marked contrast with the rarity of such affections in the mouth. In the *Journal of the American Medical Association*, March 19th, 1898, Dr. L. Jurist has published a case of membranous stomatitis which, though it clinically resembled diphtheria, was caused by the streptococcus pyogenes. A woman, aged twenty years, had an attack of vomiting and diarrhœa which yielded to treatment. Shortly afterwards the tongue began to swell; it increased to such an extent as to cause alarm lest she should be choked. The tongue was enormously swollen and protruded in a thick mass from the mouth; the appearance of the patient was anxious and distressing. The floor of the mouth and the under surface of the tongue were covered by a thick greyish membrane. There was a repulsive odour from the breath, the pulse was rapid and feeble, and the temperature was 101° F. For two weeks the general condition remained the same. The membrane spread to the inner surfaces of the lips and cheeks. There were frequent slight hæmorrhages which became freer if portions of the membranes were forcibly detached. The submaxillary lymphatic glands were enlarged, and a well-marked œdema involved the entire face and neck, extending from ear to ear. As the patient improved an examination of the throat became possible. Two oval, distinctly outlined patches were

seen on the hard palate but none on the soft palate or tonsils. After the failure of other remedies the application of nitrate of silver combined with the administration of chlorate of potash proved successful. Twice there was copious bleeding from ulceration of the tongue which was beneficial, being followed by subsidence of the inflammation. Bacteriological examination showed streptococci in conspicuous numbers but no diphtheria bacilli. A case of true primary diphtheria of the mouth has been reported by M. Thiercelin. A woman complained of pain on opening the mouth and had anorexia and a little fever. The lower surface of the tongue, which was not swollen, and the floor of the mouth were covered with a whitish-grey membrane. There were membranes on the cheeks, gums, and lower lip. The disease did not extend beyond the pillars of the fauces. The submaxillary lymphatic glands were swollen, mastication was impossible, and intense fœtor and salivation were present. Diphtheria bacilli were found in abundance in the membrane. M. Sevestre and M. Gaston have reported a series of cases of membranous stomatitis which constitute a special form denominated by them "stomatitis impetigi-nosa." It attacked debilitated children, especially those recovering from measles or whooping-cough. A whitish adherent membrane similar to diphtheritic exudation formed. The tongue was rarely attacked. In nearly all cases the disease was associated with impetigo of the face. The staphylococcus pyogenes aureus was found in every case.

THE VALUE OF THE RECEPTION-HOUSE OF ST. GEORGE'S, SOUTHWARK.

THE patron saint of England has for many years undergone undeserved neglect at the hands of the country who adopted him as her protector. But this year his day was more generally observed than for many years past and two incidents in which his name figures have been prominently brought to our notice. We give an account in another column of the opening of a new wing forming part of the cottage hospital dedicated to St. George at Bloemfontein, and only the other day the vestry of St. George's, Southwark, had to congratulate their medical officer on an outbreak of typhus fever being averted. In THE LANCET of Feb. 5th, 1898, we gave an account of the reception-house recently erected in that parish for housing those persons who are evicted for disinfection purposes, and the value of this building was exemplified at the meeting of the vestry held on April 19th, at which it was reported that a case of typhus fever imported from Kensington had occurred in a four-roomed house containing four families. These families were removed to the reception-house and their own house was thoroughly cleansed and disinfected. So far no fresh case of typhus fever has been notified. We may incidentally mention that Dr. Waldo did not present any statistical report, for the report had not been before the public health committee and he was not "allowed" to present it to the vestry until the committee had seen it. This somewhat curious method of procedure, however, makes no difference to the value of the reception-house, and we hope that other parishes in London will follow the example of St. George's, Southwark, and provide like buildings.

COCAINE POISONING.

CASES are from time to time reported of deaths from cocaine poisoning. Many of these have occurred in medical men who have treated themselves with the drug for purposes of relieving pain and have by accident or design injected an overdose. An instance of this kind occurred a few years back. The body of a young medical man was found at a railway station. In his hand was a hypodermic syringe containing morphia which he had evidently been about to inject as an antidote. He had been accustomed for some time to inject cocaine for the relief of neuralgia. On April 18th, 1898, Dr. G. Danford Thomas held an inquest at Paddington on the body of the wife of a medical man who had died after drinking a solution of cocaine. Eight weeks previously she had swallowed a quantity of laudanum from a phial which she found in her husband's bag, assigning no reason for doing so but telling him immediately after the act. Antidotes were applied and she recovered. On the evening of April 13th she remarked to her husband: "I am feeling ill," and she produced a small bottle from her pocket containing a solution of cocaine which she had abstracted from the bag whence she had obtained the laudanum previously. Both bottles were duly labelled "Poison." She said she had taken cocaine and asked that a medical man might be fetched, but all treatment was unavailing. All experience shows that a good deal of care is requisite in administering cocaine as it has again and again happened that small amounts of the alkaloid have given rise to the most threatening symptoms. Two-thirds of a grain injected subcutaneously caused the death of a woman, aged seventy-one years, in five hours, and a man died almost immediately after taking 22 grains by the mouth. Persons, however, habituated to its use can take increasingly larger doses. Among the most striking manifestations of its threatening characteristics are abnormal exaltations of the feelings, loquacity accompanied by mental incoherence, severe sweating, fall of temperature, shallow and irregular respiration, dilatation of the pupils, disturbance of vision, nausea, feeble pulse, and ultimately collapse. In persons suffering from these symptoms stimulants should be given. The inhalation of chloroform has been tried to relieve the spasms. Nitrite of amyl has also been suggested. Some medical men make it a practice to give a preliminary hypodermic dose of from $\frac{1}{8}$ to $\frac{1}{4}$ grain of morphia, according to the age of the patient. The physiological antagonism between the drugs is pronounced, so that while morphine is not an absolute antidote it is at least most valuable in counteracting the toxicity of cocaine.

OCULIST SEALS.

ANOTHER seal of a Roman oculist has been discovered recently in France and is published in the *Journal of the French Society of Antiquaries* by M. Héron de Villefosse. Unfortunately the owner's name is illegible, but the inscription preserved presents us with the titles of certainly three, and perhaps four, well-known classical collyria. The text is as follows: "Diapsor: Crocodes: E—— L—— Nardinum." The first of these remedies, diapsoricum, from Διὰ ψωρικόs, and therefore a substance whose basis was copper, was, we know from the seals, used in cases of feebleness of vision (caligo) and as a cure for scabrities and sycosis, for which see Celsus, VI., vi., 31, and Dioscorides, V., 118, col. 781. The second ingredient, crocodes, was applied for what was termed "aspritudo"—that is to say, palpebral granulations (trachoma), and is so alluded to in several seals and among the medical classics; by Aetius, I., iii., 43 col., 318 H; Marcellus, VIII., col. 280; and Celsus, VI., 6, 27. It is also quoted as a cure for diathesis (διάθεσις), which in reference to ocular disease merely indicated a morbid condition of the eyes. Of course it was Κροκος, saffron. Nard on the seals is always prescribed as a remedy for "lippitudo," incipient ophthalmia, or ophthalmia itself, see Actuarius V., 11, col. 282. The letter E, followed by a lacuna, may be the first letter of Euodes, or Euvodes, but this is merely a surmise. However, that is the only hitherto known of the collyria commencing with E referred to upon oculists' seals. A most interesting memorial of a Roman military medical officer attached to the celebrated VII. Claudian Piafidelis Legion has also been found at

Turn Severin. It is a lapidary inscription which, "with all reserve," may be approximately translated thus: "To the divine shades Marcus Valerius Longinus (son of Marcus), physician of the VII. Claudian Legion, adorned with the Senatorial ornaments of the illustrious order of the Hadrian municipality of Drubetis, lived 23 years."

THE PREVALENCE OF GERMAN MEASLES.

IT is well to remember that there is a good deal of this disease abroad. Sometimes it is taken for a second attack of measles. We have seen lately the rapid succession of the two complaints within six weeks' time. In such instances the disease is more likely to be narrowly examined and a mistake in diagnosis to be avoided. In other cases the diagnosis is not quite so easy. At one time the existence of scarlet fever is apt to be assumed and the patient possibly is sent to a hospital as so affected. In doubtful cases a little time and care will be well spent before deciding on the non-existence of true measles or of scarlet fever. After all, the differentiation can generally be made, though we have in exceptional cases to wait for the evidence of the more decided desquamation of scarlet fever. The absence of severe coryza and of high temperature, plus the different nature of the rash and the enlarged glands behind [the sterno-mastoid, will generally guide the physician aright as between German and ordinary measles, as the absence of serious sore-throat and pyrexia will help him to exclude scarlet fever. The incubation stage seems longer than that of measles and of course much longer than that of scarlet fever. According to the report of the committee of the Clinical Society of London the interval between the exposure to infection and the appearance of the rash is generally nearly three weeks.

THE LIVERPOOL CORPORATION AND THEIR WATER CUSTOMERS.

AN interesting appeal case was heard at the Liverpool County Quarter Sessions last week with regard to the Liverpool water-supply. The Liverpool corporation supply water not only to the city but to certain districts around and under a section of the Corporation Act of 1866 they are bound to supply water at constant service at such a pressure as to reach the top storey of any house situated within the district supplied by them unless the service is interrupted by drought or by frost. Some time ago an inhabitant of Prescot, which is in the district supplied by the corporation, commenced an action at the Prescot police-court to compel the corporation to carry out their statutory duties. The case was taken to the Divisional Court in London and was decided in favour of the complainant. After this decision the members of the Conservative Club of Prescot were encouraged to bring an action to compel the Liverpool corporation to give their premises a constant supply of water which had previously been withheld. From the report before us it appears that the club was supplied from a high-level tank and until nearly the end of last year water was only obtained at the club between six o'clock in the morning and six o'clock in the evening. At a previous period the water was supplied by gravitation from the reservoirs and the pressure was only sufficient to supply the first and second floors of the club during the day. The deficient water-supply caused considerable inconvenience, because the bar, lavatory, and baths had not a constant supply. In the year 1896 two cisterns had been placed in the upper storey for the storage of water. These cisterns were not supplied during the night. The members of the club had suffered from this state of things for a considerable time but the decision in the case which has just been referred to determined them to try to obtain a legal remedy for the neglect of the Liverpool authorities to carry out their statutory obligations. Complaints were made to the corporation and the town clerk promised that steps would be taken to give a sufficient supply of water and the corporation pumped water to the high-level tank during the night as well as during the day, so that a certain amount of water was supplied to the club cistern during the night. During the daytime, however, when water was taken in any quantity in the lower part of the town the amount of water obtainable at the club was insufficient for domestic use. In support of this statement the secretary, the manager, and the chairman of the club gave evidence and the presiding magistrate, after hearing witnesses for the defence, said that the bench were satisfied that the supply of water was insufficient. On behalf of the Liverpool corporation it was pleaded in the course of the trial that, in the first place, the conviction was not good because the water rent had not been paid at the date from which the fine was imposed. In the second place, it was pleaded that the Liverpool corporation could not with their present works and apparatus supply water at sufficient pressure and that they could not increase their works without Parliamentary authority. It was urged, moreover, that if the contentions of the club were correct the corporation would be compelled to erect new works from time to time to supply high buildings if such were erected. On the application of the counsel for the Liverpool corporation the magistrates agreed to state a case for the higher courts. The matter, therefore, which is of some importance, has not been finally settled, and we await the result with interest.

TRAUMATIC RUPTURE OF THE INTESTINES.

THE number of cases of traumatic rupture of the intestine unassociated with wound of the abdominal parietes which have been submitted to operation with a successful result is very small. The difficulties which surround the formation of a diagnosis are many and varied. As, however, the patients invariably die when the rupture is not sutured and the abdomen properly cleansed it is of the utmost importance that the profession should recognise the possibility of a rupture having resulted from an injury and take measures to obviate the fatal result which must otherwise follow. We hope to give our readers fuller details of three cases in a future number of THE LANCET, merely stating now their bare outlines. It is interesting to note that the three cases were all subjected to operation at one of our hospitals, St. Thomas's, where the first successful intestinal suture in London for similar injury was performed by Mr. John Croft. About two months ago Mr. Makins was called to see a man who had been run over a few hours before. At the operation an oblique tear of the ascending colon was found. This was sutured, the peritoneum was cleansed, and the man made a good recovery. The second case was that of a man, aged twenty-seven years, who had been run over when intoxicated and had been refused admission to another hospital. This patient was operated on by Mr. Battle twenty-one hours after the injury. A tear in the small intestine twelve inches from the ileo-cæcal valve was sutured and the peritoneum was cleansed, but with some difficulty. The patient's condition was very serious. We are pleased, however, to learn that there is a good prospect of recovery. The operation was performed on April 5th. Only last Sunday, April 24th, Mr. Pitts was called to see a man who had received a kick in the abdomen from a horse. He operated and sutured an opening which was found high up in the small intestine. The patient has progressed extremely well. There can be no doubt that early operation is indicated in these cases, for the sooner the opening in the bowel is closed the less

extensive will be the infection of the peritoneum and the less will be the risk of septic peritonitis which is so much to be dreaded.

THE HEALTH OF MR. GLADSTONE.

WE are sorry to learn on good authority that Mr. Gladstone is manifestly weaker, though this is not due so much to any obvious progress of disease as from a general failure of power. He retains, however, a fair amount of strength, while the appetite is satisfactory, and the pulse, though variable, is at times good. We are very glad to state that though the illustrious patient is not free from intermittent flashes of pain, these do not now appear to be of a very severe character.

IRISH OPPOSITION TO THE LONDON UNIVERSITY BILL.

OPPOSITION to the London University Bill is brewing from a somewhat unexpected quarter. The *Daily Nation* (Dublin) on Tuesday last devoted its first leading article to a passionate appeal to Irish representatives to unite in strenuously opposing the passage of the University of London Commission Bill "until and unless adequate measures are forthcoming that the Government will take steps to remedy the gross inequality of treatment between the two kingdoms." It is averred that the measure in question is to be pressed forward by the Government as soon as the Irish Local Government Bill has passed through Committee; and that if passed it "will give to England an additional university almost precisely similar in character to that for which Catholic Ireland has appealed in vain." Now we do not complain of Ireland's desire to have a Roman Catholic teaching university established in a country where so much of the higher education is carried on by Roman Catholics, but surely it is rather absurd to speak of the reconstitution of the University of London as a measure which runs parallel to the foundation of a Roman Catholic university for Ireland. We fear that our Irish friends are not well posted in the history of the movement to secure a teaching university for London, of which the present Bill is the outcome; and we trust that they will think twice before quoting this reform in the facilities for higher education in the metropolis as another "injustice to Ireland." Indeed, if the views expressed by the *Daily Nation* are accepted then the fact of the passage of this Bill should prove a powerful argument in support of their particular demand.

SIR WILLIAM BROADBENT is announced to take the chair at the annual meeting of the Medical Mission (Auxiliary to the Church Missionary Society), which will be held at Exeter Hall on Thursday next, May 5th, at 7.30 P.M. Among the speakers will be Mr. A. Neve, medical missionary in Kashmir; Dr. Herbert Lankester, physician to the Church Missionary Society; and the Rev. J. C. Hoare, M.A., missionary in China. There are a few reserved seats, tickets 1s. each, but other tickets are free on application to the secretary, Medical Committee, Church Missionary House, Salisbury-square, E.C.

THE annual dinner of the Indian Medical Service will take place at the Café Monico on Thursday, June 9th, at 7.45 P.M. Surgeon-General Sir Joseph Fayrer, Bart., K.C.S.I., F.R.S., M.D., will preside. It is particularly requested that officers intending to be present will intimate their intention at the earliest possible date to the honorary secretary, Mr. P. J. Freyer, 46, Harley-street, W.

SOME of the friends and colleagues of Dr. W. S. Playfair have arranged to give him a complimentary dinner on his resignation of the offices he held at King's College and King's College Hospital. The date is fixed for June 4th and Lord Lister will preside. Dr. John Phillips is acting as secretary.

THE British Institute of Preventive Medicine has now formally notified a change of address. After May 1st, 1898, communications should be made to Grosvenor-road, London, S.W., instead of to 101, Great Russell-street, London, W.C.

REPORT OF THE ROYAL COMMISSION ON TUBERCULOSIS.

I.—MILK.

FEW subjects have been more considered by Royal Commissions and other committees than that of bovine tuberculosis. In 1888 the subject had already attracted so much attention that it was added to the work of the Departmental Committee appointed to inquire into pleuro-pneumonia. The contagious nature of the disease was not nearly so clearly recognised at that time as it is to-day and although the recommendations of the committee were strong no decided action followed them, as there was not sufficient evidence to prove that such action would be acceptable to stock-owners. During the next year or two, owing to the stringency of some medical officers of health in condemning for the purpose of food animals which after slaughter showed traces of the disease, the butchers, on whom the loss from these seizures fell, agitated for the appointment of a Royal Commission to consider the question. This Royal Commission was appointed in 1890 to inquire into the effect of food derived from tuberculous animals on human health, and the report, delayed in consequence of the necessity of carrying out experiments to gain accurate information on the point, was presented in 1895. The conclusion of that report, shortly, was that an appreciable part of the tuberculosis which affects man is obtained through his food, chiefly from milk containing tuberculous matter. At the same time the Commissioners stated that "provided every part that is the seat of tuberculous matter be avoided and destroyed ..... a great deal of meat from animals affected with tuberculosis may be eaten without risk to the consumer." Very valuable as that report was it did not touch on the administrative procedures available for reducing the amount of tuberculous material in the food supplied by animals to man, and as that was the point with regard to which the butchers were most interested the matter was not allowed to rest. During the time that the Royal Commission had been sitting knowledge of the disease had been greatly extended. The stringent measures with regard to the seizure of tuberculous carcasses in countries such as Germany, France, and Belgium had been greatly relaxed, and through the discovery of the value of tuberculin as a means for diagnosing the disease in cattle it was thought that an important agent for eliminating the disease lay ready to hand. The time was therefore ripe for the reconsideration of the subject and in July, 1896, the present Commission which has just reported was appointed to inquire into the administrative procedures for controlling danger to man through the use as food of the meat and milk of tuberculous animals. All the seven members of the Commission sign the report, but a memorandum on the subject of compensation to owners of condemned carcasses is added by three of them, including the chairman, Sir Herbert Maxwell.

We think that the conclusions at which the Commissioners have arrived will commend themselves to the medical profession and the general public. The members have evidently availed themselves of the powers allowed to Royal Commissions to gain first hand information on the subject of their inquiry by visiting Belgium, Germany and Denmark, where the administrative measures have been worked out much more fully than has been the case in this country. In addition to the 55 witnesses whom they summoned before them, consisting principally of medical officers of health, sanitary inspectors, butchers, and dairy farmers, they visited

slaughter-houses, cow-sheds, and dairies in various parts of Great Britain and Ireland.

As was to be expected the Commissioners consider that the danger from tuberculous meat, seeing that the meat substance itself is so rarely the seat of the disease, is slight, while that from milk, for the reason that it is consumed chiefly in the raw state by infants who are peculiarly susceptible to tuberculosis of the bowels, is serious. We therefore propose to consider first the bearing of the report on the milk aspect of the question. The Commissioners are in entire agreement with the finding of the previous Royal Commission that the condition required for ensuring to the milk of tuberculous cows the ability to produce tuberculosis in the consumer is tuberculous disease of the udder. A cow with marked tuberculous disease of other organs does not, so long as the udder remains unaffected, cause the milk to be dangerous; but a tuberculous infiltration of the udder fortunately is not an early manifestation of the disease in the cow—on the contrary, it is usually secondary to disease in other organs and occurs late in the course of the disease. In the slaughter-houses of Copenhagen it has been found to occur in from 1 to 2 per cent. of tuberculous cows. Still, owing to the practice prevailing among cow-keepers of mixing the milk of all the cows, one animal with disease of the udder is a source of danger to the whole milk-supply, and that such a danger is not one to be neglected is demonstrated by the interesting investigation made on the subject by Dr. Hope, the medical officer of health of Liverpool. He found that of 144 samples of milk taken from dairymen within the city and of 24 arriving from rural districts at the railway stations, 8 samples, or 2·8 per cent., of the former and 7 samples, or no less than 29·1 per cent., of the latter produced tuberculosis after inoculation in guinea-pigs.

We regard, therefore, the recommendation "that notification of every disease in the udder shall be made compulsory under penalty on the owners of all cows" as the best and most wide-reaching of all the recommendations. Legislation hitherto has failed to touch tuberculosis in the cow, as this disease was not included among the contagious diseases of animals to which the Dairies, Cowsheds, and Milkshops Order applies, nor has it been found practicable to deal with it under the Infectious Disease (Prevention) Act, 1890. But in order to prevent the sale of milk from a cow presenting clinical symptoms of the disease, a condition in which an infection of the udder may be regarded as imminent, the Commissioners recommend the extension of notification also to cows thus affected, with power to the local authority to prohibit the sale of the milk as well in the one case as in the other and even to slaughter the animals.

The prevalence of tuberculosis among cows to a far greater extent than among bullocks and heifers is directly traceable to the ease with which the contagion may spread from one animal to another in badly ventilated cowsheds. The medical officer of health has in many cases offended the agricultural community by his insistence on the necessity of adequate cubic space in cowsheds and the Commission state it as their opinion that from 600 to 800 cubic feet for each adult beast should be a minimum in populous districts. Many will regret that they do not apply the same minimum to cowsheds in rural districts, where it is notorious that the housing accommodation is often bad in the extreme.

After reading this report the farmer will have no excuse for not setting his house in order and making an attempt to eliminate the disease. The description the Commissioners give of the success of the Danish experiments in subduing the disease by inoculating whole herds with tuberculin is most encouraging. They were given the opportunity, under the guidance of Professor Bang, whose name will be inseparably associated with the first scientific attempt to get rid of the disease, of visiting two out of the 5300 herds which have been dealt with by the Danish method. That method is, briefly, to replace a herd that may have been markedly affected by a healthy one in the course of a few years by separating the sound from the reacting animals, feeding the calves born from the first day of life on boiled milk, submitting the healthy animals once or twice a year to a fresh test, placing such as react on the other side of of a partition, and purchasing only animals which have stood the tuberculin test. Tuberculin gives trustworthy results, Professor Bang believes, in over 90 per cent. of the animals tested, but in the great majority of those which react the test reveals only latent tuberculosis. Hence it is not necessary to exclude the milk of reacting animals from human consumption unless visible signs of the disease are at the same time present, although, being tainted animals, it is advisable to sell them off gradually for the meat market. In the case of Denmark the supply of tuberculin and the services of a veterinary surgeon have been given gratuitously to the farmers by the State, and so impressed are the Commissioners with the success of the arrangement that they recommend that funds be placed at the disposal of the Board of Agriculture to carry out in this country, on the same lines as in Denmark, a similar comprehensive scheme for the elimination of the disease.

Fault will be found by some that there is no recommendation in the report that animals which react to the tuberculin test should be marked. In some parts of the country a certain amount of feeling has been aroused by the action of farmers who, after having discovered by means of the test which of their animals were affected, have at once drafted them off for sale, generally at a place some distance from their farm, without a declaration that the animals had reacted. The point raises a nice question in commercial morality, but the fact that there is no mention of the desirability of marking such animals in the Report must be taken, we suppose, to mean that the Commissioners are so impressed with the value of tuberculin that they do not wish to place any obstacles in the way of its general introduction. Later, when it is seen how far the agricultural community are prepared to take advantage of the test, some regulations with regard to the use of tuberculin will have to be framed.

In a second article we propose to discuss the report in regard to the recommendations of the Commissioners on the subject of tuberculous meat.

MEDICINE AND THE ALLIED SCIENCES AT THE PARIS EXHIBITION OF 1900.

MEDICINE and the allied sciences will occupy an important place at the forthcoming international exhibition to be held in Paris in 1900. By the courtesy of the secretary of the committee of organisation, M. Mazure, and of the Dean of the Faculty of Medicine, our Paris correspondent has been supplied with information which although dealing with what are at present merely projected arrangements yet possesses a great deal of interest. To begin with, a general survey of the arrangements made for foreign exhibitors shows that they will not, as heretofore, have special sections allotted to them—sections which, in fact, formed a number of small separate exhibitions, naturally enough of the most various sizes. This system certainly had the advantage of leaving the special commissioners for the section from each country a free hand in the organisation of their own exhibits and at the same time of giving visitors some idea of the geographical and statistical importance of the various productions and industries peculiar to each nation. But at the same time it was open to the objection of breaking up the exhibition into groups of the most varying size. At the exhibition of 1900 the foundation of a group will not be nationality but the nature of the object on exhibition. According to present arrangements there will be no special national sections but the various countries will exhibit side by side those objects which are illustrative of the same industry. Comparison therefore will be rendered far more easy and the visitor who has a special interest in any one subject will find all the elements necessary for a complete answer to his inquiries displayed before his eyes in a very compact and complete manner. On the other hand, it is possible that the new system will have the effect of giving to each section the appearance of a *salle de concours*, where the public will run the risk of receiving a superficial and inexact impression with regard to the importance of the same industry in the different countries represented; for it is evident that distance, cost of transport, &c., will play a considerable part in the extent of these installations, Australia, for example, on account of being so much further off, being less able than Belgium to have itself well represented in each group.

Having made these general observations we may proceed to examine the various divisions of the different sections of medicine and the allied sciences. These are, as a matter of

fact, very well shown upon the plan drawn up by the committee of organisation, but the plan exhibits various inconveniences which are inevitable in any classification, and those critics who find fault with the arrangements would probably have done the same on other grounds if the plan had been different. By far the larger part of the exhibition allotted to medicine is catalogued under two groups—namely, the third and the sixteenth. The third group is that including instruments and various things common to literature, science, and art. In this group Class 16 is given up entirely to medicine and surgery. The President of the committee is Dr. Paul Berger, Professor of Clinical Surgery at the Faculty of Medicine and surgeon to the Hôpital de la Pitié. This portion of the exhibition will contain material for practical medical and surgical work, as the following enumeration shows:—Appliances, apparatus, and instruments for anatomical, histological, and pathological work; anatomical specimens both normal and pathological; histological and bacteriological preparations; apparatus for sterilising instruments and dressings; instruments for the examination of medical cases both general and special; instruments and apparatus for the examination of surgical cases, general, local, and special; dressings; artificial limbs and similar appliances; orthopædic apparatus; instruments and the like for the surgical treatment of hernia; medical gymnastic apparatus; materials, instruments, and apparatus for special therapeutics; dental instruments; various forms of apparatus for the infirm, the sick and the insane; outfits and cases of instruments and drugs for military and naval surgeons; materials for the use of the wounded on the field of battle; apparatus for restoring the apparently drowned or asphyxiated; and instruments and apparatus used in veterinary surgery.

It must be noticed that the exhibits concerned with military medicine both by sea and land are also to be found under another class—namely, Class 121, Group XVIII., that devoted to hygiene and sanitation—and that veterinary instruments also will be found a second time in Class 35, Group VII. (Agriculture), also a great many instruments and the like will be found again in Class 98, Group XV., which is allotted to the caoutchouc and gutta-percha industry, and in Class 27, Group VII., which includes the various applications of electricity. In Group XVI., allotted to social economy, hygiene, and *assistance publique*, it will be found that the medical profession is almost entirely concerned with two of the subjects.

Class 111, namely Hygiene, will occupy a part of the enormous gallery of machinery, alongside that allotted to agriculture probably. The president of the Committee of Organisation is Professor Brouardel, dean of the Faculty of Medicine of Paris. Here are the provisional divisions according to the official programme. (1) Science of hygiene: historical exhibition of the progress of hygiene; the application of the discoveries of Pasteur to the prophylaxis of infectious diseases; laboratory work, both chemical and bacteriological, in its application to hygiene; researches on the transmissibility of infectious maladies; methods and apparatus for disinfection; methods for the collection and conveyance of drinking water with a view to preventing contamination. (2) The hygiene of the person and of the dwelling house; measures of precaution against transmissible maladies; immunity; "vaccination" as a preventive of small-pox and hydrophobia; application of the rules of hygiene in the choice of materials for building; warming, ventilating, lighting, &c.; water supply; apparatus for baths and hydrotherapeusis; sewage disposal. (3) Hygiene with regard to public buildings and associated dwellings (*établissements collectifs*): schools, factories, workshops, hospitals asylums, public halls, theatres, and the like. (4) Hygiene in rural communities: conditions indispensable for the health of rural habitations; municipal sanitary regulations; rural police (*police de la voirie*); storing, transport, and utilisation of various manures; the protection of waters intended for drinking. (5) Hygiene and sanitation of towns: street commissioners (*voirie*); cleansing the public streets and gutters and sweeping; building regulations (such as the number and height of the storeys, size and ventilation of inhabited rooms, and size of courts and alleys); emptying of cesspools; water-supply for a town, apparatus for filtering and sterilising; sewage disposal, disinfection of sewage, irrigation grounds; utilising of waste and offal; sanitary municipal arrangements; health office; methods of collective defence against infectious maladies; transport of those suffering from contagious diseases; isolation, disinfection of the belongings and the houses of the infected; inspection of substances used for food; inspection of abattoirs and private slaughter-houses; municipal laboratories; cemeteries, and apparatus for cremation. (6) Protection of frontiers against epidemic diseases: (*a*) by land—medical inspection at the frontier, infirmaries, and disinfection at frontier railway stations; (*b*) by sea—sanitation of seaports, sanitary organisation, former lazarets, sanitary inspection stations, medical staff, and disinfection on board ship. (7) Food products and objects in common use: control of food products, examination for adulterations, various processes for the preservation of foods; inspection of mineral waters both natural and artificial; objects in common use and the progress of hygiene with regard to such. (8) Mineral water stations and sanatoria: analysis of mineral waters, methods of collection and safeguarding the springs, various methods of medication by mineral waters and apparatus destined to apply them, such as bathing pools, apartments for inhalation, sprays, &c. (9) Sanatoria, thermal stations, general disposition of such places, aspect, covered-in promenades: thermal establishments, huts, baths, douches; preventive and antiseptic measures, especially in those places frequented by tuberculous patients; bottling and preservation of mineral waters. (10) Sanitary and legal statistics: death- and birth-rates; epidemic mortality; sanitary legislation.

In Class 112, that allotted to the *assistance publique* and organised under the presidency of Senator Theophile Roussel, which will be housed in the space allotted in 1889 to the section of the liberal arts, will be found many sections of interest to the medical profession. (2) Protection and help during infancy; general organisation for protection and help during infancy: protection and help for the infant before birth by extending the same to the mother, such as asylums, workrooms, maternity societies, private and public lying-in hospitals, convalescent homes; protection and help for the child after birth; *crèches*, institutions for children in early life, for foundlings, deserted children, orphans, and those morally abandoned; help for sick and weakly children, dispensaries, hospitals, infirmaries, and the like. (3) Help for adults: for those able to work, clubs, labour exchanges, bureaux, night shelters, mendicity societies; for the sick: help at home, gratuitous medical attendance and medicine, hospitals including regulations, organisation, medical and surgical service, special service for contagious diseases; for the aged: asylums and country farms, infirmaries. (4) Help for the insane: public and private asylums, infirmaries, *maisons de santé*; help by means of field colonies; special institutions for epileptic and feeble-minded children; educational methods. (8) Staffs of charitable establishments; training schools for nurses both male and female.

To these, the principal groups, must be added sundry other sections dealing with medical matters which will be found under other heads of classification. Thus, for instance, the teaching and material for it given by the Faculty of Medicine comes under Group I. (Education), Class 3 (Higher Education and Scientific Institutions). There, too, will be found the following sections which concern us: (1) Legislation, organisation, and general statistics of higher education; various institutions and establishments for the same; locality, plans and models, fittings, furniture, and other material for education; supply and renewal of the professorial staff; régime, schemes of study, methods, &c.; results. (2) The great scientific bodies; learned societies; work and publications; scientific missions.

With regard to the medical library and the medical press, their place is not yet definitely decided. There is a class—namely, Class 13, Group III.—where the books and journals will be exhibited. But M. Mazure, in answer to our correspondent's inquiries on this subject, seemed to think that these publications would be of too special a nature to be exhibited with the general press and would perhaps be found under Class 3 (Higher Education) or more probably in Class 111 (Hygiene).

Pharmacy takes up Class 86, Group IV. (Chemical Industries). A place is reserved there under the title of "Raw Pharmaceutical Material, Simple and Compound Drugs." Medicinal and pharmaceutical plants will be in Class 41 (Agricultural Products other than those intended for Food), Group VII. (Agriculture).

Finally, in Class 54 (Machinery, Implements, and Products of Crops) will be found plants, roots, barks, leaves, fruits obtained without cultivation, used by herbalists, druggists, dyers, and others.

In addition to the exhibition proper the science of medicine will be represented by a very large congress. As

in 1889 all the learned societies in France will organise a congress for the reception of their foreign *confrères*. A special building is in course of erection at present on the right bank of the Seine, close to the Alma Bridge, and in this building the congress meetings will be held. There will be a large hall which will serve not only for lectures and the like but also for international musical and dramatic entertainments. The organisation of the various meetings is in the hands of a special department which has already set to work. M. Gariel, the professor of Physic at the Faculty of Medicine, is the head of this department. There will be altogether from 200 to 230 different congresses, of which some thirty will have to do with medical science pure and simple. The most important will be, as has been the case at every exhibition, the congresses of the Therapeutical Society, of Forensic Medicine, of Surgery, of Urology (a new departure) and of Hydrology. All these congresses are divided into twelve sections and Section VI. is devoted to the medical sciences. Probably, too, they will be represented in certain other sections, such as Section IV. (Physical Science and its Applications), Section V. (Natural Sciences, Anatomy, Physiology, Anthropology), and Section X. (Social Science, Social Economy, Hygiene, *Assistance publique*, and the like).

Besides these, the International Congress of Medicine, will take place at Paris in 1900. To M. Lannelongue, M. Chauffard and others was intrusted at Moscow, when it was decided that the next Congress should be held at Paris, the task of organising it, and they have already begun to prepare. The question has arisen whether the various medical congresses of separate societies of which we have already spoken will be incorporated with the grand International Congress, of which they might form sections already organised and arranged, thanks to the initiative taken by the various presidents and bureaux. This plan would certainly simplify the organisation of the International Congress and, in addition, visitors who came to study one particular branch would find everything about it ranged under one and the same meeting.

Negotiations are still going on but unless some decision is soon arrived at the International Congress will be held and organised independently of the sectional congresses, although many of its sections will simply double the parts of the others. The reason of this is presumably that the organisers of the International Congress wish to nominate for themselves the presidents of sections and are not willing to accept those gentlemen who are already presidents of the various society congresses. The International Congress will probably be held at the beginning of August, 1900, and the smaller congresses during the month of July, so as to avoid the necessity of foreign medical men making two journeys.

The French Medical Press Association has decided to organise a committee for the reception of foreign medical men, so that they will have a place where they will be able to obtain all information concerning Paris, the Exhibition, and the Congress.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE nineteenth meeting of the Royal Commissioners was held in the Council Chamber of Westminster Town Hall on April 25th. With the exception of Sir George Barclay Bruce all the Commissioners were present during the whole of the sitting.

The examination of the City Remembrancer was concluded and Sir Arthur Arnold gave evidence on behalf of the London County Council. The evidence of the City Remembrancer had reference chiefly to the sinking fund which is invested by the Chamberlain of the City of London and with the exception of details concerning the investments little information was added to the evidence previously given. Sir Arthur Arnold was examined on a "private and confidential" printed statement which was put in on his behalf for the information of the Commissioners. This statement, it appeared in the course of the examination, was not written by the witness and he did not seem acquainted with the details which it contained, but he said it was corrected by him. Towards the end of the sitting the Chairman asked who composed the "little book," but Sir Arthur Arnold did not satisfy the Chairman's curiosity on this point.

The CITY REMEMBRANCER, in answer to the CHAIRMAN, said that the Water Companies' Sinking Fund was invested in the name of William James Richmond Cotton, Chamberlain of London. A table which he handed in gave the names of the companies in whose securities the money was invested, the date at which the dividends had been paid, the price at which the stock was purchased, the date of purchase in each case, the cost at which the stocks were bought, including stamps and brokerage and the "price per cent." at which the securities were bought. The companies in which the sinking fund is invested are the East London Waterworks Company, the Lambeth Waterworks Company, and the Southwark and Vauxhall Water Company. The first purchase of stock was made on April 13th, 1891, and the last on April 6th, 1898. The total amount of the money received and invested is £22,424 17*s.* and the total nominal amount of stock purchased is £12,015. The purchases of the stock are not made under seal of the Corporation but in the name of William James Richmond Cotton, Chamberlain of London. The question arose as to who would be responsible in case of the bankruptcy of the Chamberlain, and the counsel for the water companies suggested that the title "Chamberlain of London" was a description of the purchaser and said that a company would be obliged to transfer the stock on the signature of the holder and that, in fact, the description "Chamberlain of London," from a legal point of view, did not mean more than "esquire" as a description of the occupation of an individual holder of the stock.

The CITY REMEMBRANCER expressed the opinion that the official auditor of the water companies' accounts had not sufficient authority and he understood that he had experienced some difficulty in carrying out the work assigned to him. He said, however, in answer to the CHAIRMAN, that he had not received any written complaint from the auditor and the CHAIRMAN then stated that the Commissioners would wish to have an opportunity of examining the auditor himself.

With regard to the investment of the sinking fund in the water companies' stocks the witness pointed out that it was necessary that the Chamberlain should invest the money in the stocks of the companies from which the money for the sinking fund was received. The objection to investing the money in this way was that the purchaser who was obliged to buy a certain stock was, as it is called in the City, "making a market against himself." The original idea of the sinking fund was that it should be used for the purchase of stock and that the stock so purchased should be cancelled, but this arrangement had to be altered. On behalf of the water companies it had been urged that it would not be fair for the sinking fund provided by one company to be used for buying up the shares of another company and that the money ought to be used in the purchase of the stock of the company from which the money had been obtained, and this contention had received parliamentary sanction.

Mr. BAGGALLAY, Q.C., examined the witness on behalf of the water companies with regard to the purchase of their undertakings, and the CITY REMEMBRANCER said that if the purchase were made it should be done under a special tribunal. He did not think, however, that a purchase could be effected under any other terms than those of the Land Clauses Act and he was opposed to the purchase.

The London County Council was not represented by counsel, but in the course of the sitting Mr. CRIPPS, Parliamentary Agent for the London County Council, interrupted the proceedings more than once and was called to order by the Chairman, who said that he did not think his intervention was necessary.

Mr. BAGGALLAY, Q.C., asked the City Remembrancer some questions as to the old London Bridge Waterworks, but the CHAIRMAN thought this examination unnecessary.

Sir ARTHUR ARNOLD, in answer to the CHAIRMAN, said he had been an alderman of the London County Council and was formerly the chairman of that body. In the year 1895 he was appointed by the London County Council to see the chairmen of the different metropolitan water companies with regard to the purchase of their undertakings. As the result of the interviews he had with the chairmen he said that the impression he obtained and still retained was that there was no unwillingness on the part of some of the companies to sell their undertakings on fair terms. In answer to the CHAIRMAN the witness said that he was not authorised to

offer any terms of purchase and that he had no authority to negotiate with regard to price and no authority to agree as to any basis for the assessment of price. The interviews which he had with the chairmen of the water companies were, he considered, private and he would not violate the confidence reposed in him.

Mr. PEMBER, who represented four of the water companies, assured the Chairman on their behalf that the witness was quite at liberty, as far as they were concerned, to answer any questions which he might wish. Counsel on behalf of the remaining companies immediately gave the same permission, but the witness declined to take advantage of it.

The CHAIRMAN remarked that a negotiation in which the agent was not empowered as to what he should ask or what he should concede was a peculiar one. What was the negotiation about? Was anything said about price? If he did not condescend to consider the question of price or the terms on which arbitration should take place he could not understand why he was sent. The witness replied that he discussed various matters with the chairmen but that he was unwilling to report any part of their conversations.

The CHAIRMAN proceeded to question the witness with regard to the composition of the London County Council. Witness said that it consisted of all sorts and conditions of men and that it was of an almost ideal character. The Chairman said one of the witnesses who had given evidence before the Commissioners had said that the London County Council was conducted on party lines, that the elections were managed by party agents, and that the members of the Council had a party organisation with leaders and whips. The witness took a general exception to these allegations, but he did not deny the specific statements which had been made and which were put to him in detail by the Chairman.

With regard to the amount paid for wages the witness said that the London County Council had over 7500 employés and that many of the members were of the opinion that the Council should endeavour to get the character of being "a good employer of labour," by which he meant that the highest current rate of wages should be paid to all the people employed. Labour members were occasionally against an increase of wages.

The witness was asked whether he thought it would be necessary that any control should be exercised over the London County Council should that body become the water authority for London. The witness, in reply, said that he thought it would not be necessary, but that for his own part he would like it, "to make assurance doubly sure." He thought that the advantages which would accrue to the people in case of purchase were chiefly that they would be able to raise money more easily than the present water companies and that there would be "unity of management." He thought the arbitration for purchase should be "full, free, fair, and open." He objected to arbitration under the Land Clauses Act because of "technical rules" which, he said, came into force under them.

In answer to Mr. CRIPPS, Q.C., the witness said that he had had very little experience of the working of the Land Clauses Act and Mr. Cripps remarked that he himself had had a good deal of such experience and that the "technical rules" mentioned by the witness did not exist.

THE ROYAL ACADEMY, 1898.

THE one-hundred-and-thirtieth exhibition of the Royal Academy of Arts will be open on Monday next to the public, who will find on the walls of Burlington House a collection of pictures quite up to the usual standard, many of which they will feel that they have seen before, so faithfully have the artists reproduced, both in subject and treatment, the kind of work which is associated with their names. Mr. T. S. Cooper's various pictures of clean cattle in clean meadows, Mr. Marcus Stone's "A Welcome Footstep," Mr. Peter Graham's two canvases representing Scotch moors and shaggy cattle, Mr. B. W. Leader's "Where Peaceful Waters Glide," Mr. H. B. W. Davis's "Under the Greenwood Tree," and Mr. F. Goodall's Egyptian scenes are all exactly like previous pictures by these artists; and other less established favourites have this year elected to follow closely in the wake of their previous successes—facts which give to the walls of the Academy an extraordinary air of familiarity.

The chief features of the exhibition are Mr. Sargent's splendid portraits of Mr. Asher Wertheimer, Mrs. Wertheimer, and Lord Watson. They are vivid and life-like to a degree, and even the veteran M. Carolus Duran's portraits, two of which are hanging in the sixth gallery, must give place to them in their quality of uncompromising truth. But next to Mr. Sargent's portraits M. Carolus Duran's portrait of the Countess of Warwick is the best picture in the Academy.

Of the Academicians, the President's great picture "The Skirt Dance" is a gorgeous classical composition; Mr. Herkomer has a bad portrait of Mr. Herbert Spencer and a very large picture of the Crimean veterans cheering the Queen during the Jubilee procession; Mr. A. C. Gow has two pictures in his usual finished precise manner, a manner which makes the canvases around look blurred, hot and confused; Mr. G. D. Leslie has a picture of Arlington Row, Gloucestershire, which would lead us to believe that distance at Arlington does not alter the view, for the further the buildings recede from the eye the more distinct do they become; Mr. G. H. Boughton's "Road to Camelot" is a very pretty piece of fancy; Mr. Orchardson's "Trouble" is exactly like his well-known pictures in the Tate Gallery, and, like them, is admirably painted; and Sir William Richmond does not exhibit.

The best pictures in the exhibition outside the portraits are contributed by Mr. Frank Bramley, Mr. George Clausen, Mr. Stanhope Forbes, Mr. David Murray, and particularly Mr. H. H. La Thangue with an excellent picture entitled "A Sussex Cyder Press" and Mr. E. A. Abbey with his "King Lear" among the Associates; and among the outside contributors by Mr. T. C. Gotch, Mr. Chevallier Tayler and Mr. F. Brangwyn with his clever "Story." Mr. Albert Goodwin's "Under the Roof of the World" is a gorgeous piece of phantasy and Mr. Melton Fisher with his "In Realms of Fancy" thoroughly deserves his place on the line. On the whole we think that the drawing is above the average, but this may be accounted for by the fact that artists have set themselves fewer anatomical problems than usual owing to the number of nude studies being much less than in former years. Mr. H. Draper's "Lament for Icarus" is one instance of good anatomy, and as a triumph over anatomical difficulties Mr. W. Goscombe John's statue, "The Elf," deserves special praise from us. Among the water-colours two little landscapes by Mr. Leopold Rivers are well worth notice and in the sculpture room Mr. and Mrs. Nelson Dawson show some of their charming metal and enamel work.

The Academy this year contains but two medical portraits—Mr. Anderson Critchett, by Mr. Frederick Goodall, and Mr. T. Pickering Pick, by Mr. P. R. Morris. The former is a good picture, the latter strikes us as an inadequate portrait of a handsome man. The sitter, perhaps, may be responsible for the execrable necktie, but the artist has put a pudginess into Mr. Pick's face which has no real existence.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Epidemic Measles in the Borough of Lancaster, by Dr. THEODORE THOMSON.[1]—This report relates to the occurrence, between September, 1896, and July, 1897, of a severe epidemic of measles in Lancaster, a borough with a population estimated at about 38,000. During this period no fewer than 1185 cases of measles became known to the sanitary authority, while in the same period 51 deaths from the disease were recorded. By the provisions of a local Act measles has since 1888 been compulsorily notifiable in Lancaster. The account given by Dr. Thomson of the administrative measures adopted in dealing with the outbreak thus becomes of particular interest, the more so as Dr. Thomson has during recent years made a special study of the means available to sanitary authorities in repression of this disease. The question first arises, how many of the cases occurring during the epidemic were notified by the medical practitioner, and how many, on the other hand, were notified solely by the householder? Local authorities

[1] London: Eyre and Spottiswoode, E st Harding-street, E.C. Edinburgh: John Menzies and Co. Dublin: Hodges, Figgis, and Co. 1898. Price 3d.

very seldom demand from the latter fulfilment of his statutory duty of notifying, and this circumstance is often used to throw doubt upon the utility of making compulsory the notification of any disease, such as measles, in which frequently no medical aid whatever is sought. It is instructive, therefore, to find that in this Lancaster epidemic information of the occurrence of cases appears to have been fairly complete. No fewer than 461 cases were notified by parents only, as against 672 by medical attendants only and 49 both by parents and medical men. Householders had, in fact, notified as many as 43 per cent. of the total. Dr. Thomson gives a numerical analysis of measles notifications in Lancaster between 1889 and 1896. The figures, he points out, indicate that in some of these years householders have not always shown the same readiness in notifying measles. In years of conspicuous measles prevalence common report, as well as public notice from the sanitary authority, brings the necessity of notifying more frequently before them. In years when the prevalence is small, on the other hand, the householder becomes less mindful of his duty: thus only 9 out of a total of 46 cases in 1894 were heard of otherwise than through the medical attendants. But, as Dr. Thomson observes, the value of measles notification is bound to differ according to the circumstances under which notification has taken place. It is precisely in the inter-epidemic periods that its value is greater, for then timely and complete information may enable sporadic cases to be dealt with so as to materially lessen the chance of their giving rise to an epidemic. It would seem that towards the end of 1896 there were in Lancaster a number of scattered cases as to which, whether they were known to the sanitary authority or not, little effective action was taken. The later course of the epidemic tends to suggest that its rapid extension in January and February, 1897, was aided by schools. Closure in February of the public elementary schools seems to have produced a marked decrease in the amount of measles in the district. A recrudescence occurred a fortnight after April 22nd, when these schools were reopened. The majority of private schools and Sunday schools, on the other hand, were not closed, although the corporation are empowered by local Act to order temporary closure of such schools. Dr. Thomson notes that the chief incidence of the disease on children attending private schools occurred at a time when the epidemic was otherwise on the wane, and points out that neglect to deal with these schools and with Sunday schools must needs have diminished the value of closing the public elementary day schools. Other measures adopted with a view to preventing the spread of measles appear to have been open to objection at several points. Visits were paid to invaded houses by the sanitary inspector, but this officer, who was unaided in the performance of his duty, was unable to do more than make a single visit in each instance and hence the advice which he gave with regard to isolation of the sick was probably in many cases soon disregarded. The medical officer of health, who is also in general practice, was similarly without assistance during the epidemic. Notwithstanding the advantages which might have been gained in the early weeks of the outbreak by isolating cases in hospital the Lancaster Fever Hospital was not utilised for measles patients at any time during the epidemic. The school attendance officer and school teachers were systematically informed of measles occurring in families of which members attended school, but here again no information was afforded to teachers in Sunday-schools. No disinfection of rooms or articles was practised during the epidemic. In short, this report bears out the view which, thanks in the main to Dr. Thomson's previous work, has now come to be generally adopted. If a sanitary authority desires to have control of measles its administrative measures must be thorough at all points, both in epidemic and inter-epidemic periods. With Dr. Thomson's report to guide them it may be hoped that the corporation will in future make still better use of their exceptional facilities for the repression of epidemic measles.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 7202 births and 3905 deaths were registered during the week ending April 23rd. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 21·5 to 19·5 per 1000, further fell last week to 18·1. In London the rate was 17·9 per 1000, while it averaged 18·3 in the thirty-two provincial towns. The lowest rates in these towns were 8·4 in Croydon, 10·9 in Portsmouth, 13·6 in Brighton, and 13·8 in Swansea; the highest rates were 20·5 in Bradford and in Leeds, 21·0 in Salford, 23·8 in Newcastle-upon-Tyne, and 24·6 in Sunderland. The 3905 deaths included 472 which were referred to the principal zymotic diseases, against 516 and 488 in the two preceding weeks; of these, 211 resulted from measles, 121 from whooping-cough, 48 from diphtheria, 32 from diarrhœa, 31 from "fever" (principally enteric), 28 from scarlet fever, and 1 from small-pox. No death from any of these diseases was recorded last week in Huddersfield; in the other towns they caused the lowest death-rates in Hull, Croydon, Portsmouth, and Brighton; and the highest rates in Newcastle-upon-Tyne, Salford, Leicester, and Sheffield. The greatest mortality from measles occurred in London, Bristol, Leicester, Leeds, Sheffield, and Halifax; and from whooping-cough in Salford, Oldham, Sheffield, and Gateshead. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 48 deaths from diphtheria included 31 in London, 3 in Cardiff, and 3 in Liverpool. One death from small-pox was registered in Sunderland, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment last week in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2377, 2421, and 2384 at the end of the three preceding weeks, had further declined to 2334 on Saturday last, the 23rd inst.; 241 new cases were admitted during the week, against 239, 234, and 217 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 372 and 305 in the two preceding weeks, further fell last week to 283, and were 96 below the corrected average. The causes of 39, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Manchester, Leeds, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Norwich, Leicester, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 24·2 to 22·5 per 1000, further fell to 22·0 during the week ending April 23rd, but exceeded by 3·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Leith and 19·7 in Edinburgh to 26·5 in Dundee and 28·9 in Perth. The 663 deaths in these towns included 26 which were referred to measles, 25 to whooping-cough, 20 to diarrhœa, 6 to scarlet fever, 6 to diphtheria, and 5 to "fever" (principally enteric). In all, 88 deaths resulted from these principal zymotic diseases, against 105 and 79 in the two preceding weeks. These 88 deaths were equal to an annual rate of 2·9 per 1000, which was 0·7 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 23, 24, and 14 in the three preceding weeks, rose again to 26 last week, of which 22 occurred in Glasgow and 4 in Edinburgh. The deaths referred to whooping-cough, which had been 44 and 27 in the two preceding weeks, further declined to 25 last week, of which 16 were recorded in Glasgow and 3 in Aberdeen. The 6 fatal cases of scarlet fever showed a decline of 5 from the number in the preceding week, and included 3 in Glasgow. The deaths from diphtheria, which had been 9 and 4 in the two preceding weeks, rose again to 6 last week, of which 3 occurred in Glasgow and 2 in Aberdeen. Of the 5 fatal cases of "fever" 3 were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 157 and 164 in the two preceding weeks, declined to 152 last week, and were 13 below the number in the corresponding week of last year. The causes of 37, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·3 and 27·1 per 1000 in the two preceding weeks, declined again to

23·3 during the week ending April 23rd. During the past four weeks the death-rate in the city has averaged 27·5 per 1000, the rate during the same period being 19·6 in London and 20·8 in Edinburgh. The 156 deaths registered in Dublin during the week under notice showed a decline of 26 from the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against 9 and 10 in the two preceding weeks; of these, 5 resulted from scarlet fever, 3 from diarrhœa, 2 from whooping-cough, 2 from "fever," 1 from diphtheria, and not one either from small-pox or measles. These 13 deaths were equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 2·8 in London and 1·8 in Edinburgh. The 5 fatal cases of scarlet fever considerably exceeded the number recorded in any recent week. The deaths referred to different forms of "fever," which had been 3 in each of the two preceding weeks, declined to 2 last week. The 2 fatal cases of whooping-cough were within one of the number in the preceding week, and the mortality from diphtheria also showed a decline. The 156 deaths in Dublin last week included 22 of infants under one year of age, and 41 of persons aged upwards of sixty years; the deaths of infants showed a slight increase, while those of elderly persons were considerably below the number recorded in the preceding week. One inquest case and 1 death from violence were registered; and 60, or more than a third, of the deaths occurred in public institutions. The causes of 6, or nearly 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

NAVAL MEDICAL SERVICE.

THE under-mentioned Deputy-Inspectors-General of Hospitals and Fleets have been promoted to the rank of Inspector-General of Hospitals and Fleets: Thomas Henry Knott and George Maclean. The under-mentioned Staff-Surgeons have been promoted to the rank of Fleet-Surgeon: Charles James and George Robert Deighton Charlton.

The following appointments are announced:—Surgeons: William Hackett to the *Cambridge* and Percival M. May to the *Victory*, additional.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel William B. Miller to be Brigade-Surgeon-Lieutenant-Colonel, vice L. A. Irving, retired. Surgeon-Lieutenant-Colonel George D. Bourke to be Brigade-Surgeon-Lieutenant-Colonel, vice A. A. Macrobin, retired.

Surgeon-Lieutenant Phillips proceeds to Windsor for duty with the Royal Horse Guards during the absence of Surgeon-Captain Rayner, who proceeds for service under the Foreign Office as Medical Officer to the Commission for Delimitation of the Anglo-Portuguese Frontier in South-East Africa. Surgeon-Major Carleton is transferred to Dublin for duty. The following officers have embarked on board the steamer *Niger* for Sierra Leone: Surgeon-Major Sutton and Surgeon-Captain Cockerill. Surgeon-Lieutenant-Colonel Fenn, C.I.E., proceeds to Dover for duty.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the retirement from the service of the under-mentioned officers: Brigade-Surgeon-Lieutenant-Colonel Sir Alfred Swaine Lethbridge, M.D. Aberd., K.C.S.I., Bengal Establishment (dated April 1st, 1898), and Surgeon-Lieutenant-Colonel Dhanjisha Navroji Parakh, Bombay Establishment (dated March 14th, 1898).

THE GREY OIL TREATMENT OF SYPHILIS.

Dr. Touren of the French navy has an interesting article in the *Archives de Médecine Navale* for April, 1898, on the treatment of syphilis by intra-muscular injections. At the Moscow Congress Dr. Gaucher of Paris enunciated three propositions: (1) mercurial injections in the treatment of syphilis should be the exception and not the rule; (2) when injections are employed the soluble salts of mercury are preferable to the insoluble; and (3) if an insoluble salt has to be used the "grey oil" is the least objectionable. After five months' experience in charge of the Saint-Mandrier venereal wards Dr. Touren is in a position to disagree with the first two propositions, but with the third he is in accord. In civil life, he says, the administration of mercury by the mouth may be best, but in a military or a naval hospital this is certainly not the case. In the first place there are not only some patients who keep their sores open or create fresh ones wilfully but also others, more numerous still, who make away with their medicine. Secondly, it is universally acknowledged that in warm climates the digestive tract is peculiarly liable to derangement and should therefore be treated with circumspection. Intra-muscular injections enable the physician to administer mercury safely, expeditiously, and without any danger of digestive complications, while at the same time they ensure the ingestion of the drug as prescribed. There is therefore no valid objection to the universal employment of this method of treatment. In support of his second proposition Dr. Gaucher asserted that the administration of insoluble salts was a pharmacological heresy: *corpora non agunt nisi soluta;* but Dr. Touren found that although the symptoms quickly disappeared when a solution of mercury perchloride was injected they invariably returned with equal rapidity. In his opinion a clinical heresy was a far worse evil than a pharmacological heresy, so he preferred to adhere to the drug which gave him the best results. In Dr. Touren's hands the "grey oil" answered all requirements. The injection was painless, the patient could walk about immediately afterwards, salivation rarely showed itself and quickly yielded to an application or two of iodine, diarrhœa only occurred once, and, lastly, the mercury was absorbed with regularity and very slowly, the latter fact possibly accounting for the permanency of the cure. The formula adopted was as follows: purified mercury, 20 grammes; lanoline, 5 grammes; and vaseline, 35 grammes. The third of a Pravaz syringeful was injected at intervals of fifteen or twenty days and as a rule three or four injections sufficed to ensure the disappearance of all transmissible symptoms. When first he took charge of the wards Dr. Touren used the yellow oxide of mercury in a few cases, but the resulting pain was so severe and the absorption of the drug so irregular that he promptly gave it up. He did not venture to employ calomel because Balzer says it causes great agony when injected.

SIR EDWIN COLLEN'S VINDICATION OF THE MEDICAL SERVICES IN THE LATE INDIAN FRONTIER WAR.

IN the debate at Calcutta on the Indian Budget on March 28th last Sir Edwin Collen, the Military Member of Council, in the course of his speech on the military expenditure and the conduct of the late frontier war, alluded, among other matters, to the charges which had been made against the medical department. Sir Edwin Collen said that anyone who is a student of military history knows perfectly well that no campaign is ever conducted without an immense number of criticisms, both reasonable and unreasonable; and perhaps it is peculiarly a vice of the present day that credence is given to every kind of story which is, or appears to be, injurious to those who have the management of affairs. "Now, I suppose there is no department which has done more admirable work in the late campaign than the medical department, not only in the campaign itself but also in the treatment of the sick and wounded in the great hospitals that were formed. A large general hospital was opened at a station in the North of India. A newspaper at home published a report affirming that all the arrangements were as bad as they could be, that there was an insufficient staff, that the patients slept on the ground, and that the equipment was defective; that, for example, there were several serious cases of abscess of the liver and only three feeding cups. Now what are the facts? There was an ample staff: 16 medical officers and 18 assistant surgeons, and some nursing sisters; no patients ever slept on the ground; there were excellent barracks as well as tents; there was an ample supply of every kind of hospital equipment. There was not a single case of abscess of the liver, and there were forty feeding cups instead of three; while there was not a single death during the whole of the time the hospital was open. I merely make this statement to show how absolutely ill-founded many of the reports are."

SURGEON-LIEUTENANT-COLONEL LAWRIE ON PLAGUE IN THE NIZAM'S DOMINIONS.

Surgeon-Lieutenant-Colonel Lawrie has, according to the *Times of India*, issued a report on the plague and inoculation. His conclusions, based on personal researches, are that the infection is excessively and in a most complex

manner widespread, and that the area round Ganjoti and Umerghi constitutes by far the most important focus of infection in the Nizam's dominions. 550 deaths from plague have been reported since the epidemic first appeared. The plague is, he thinks, just the kind of disease in which poison might be looked for in discharges or exudations from buboes, either on the surface or the interior of the body. The suppurating buboes directly infect clothes, beds, bedding, and floors of houses. The bacillus of plague indicates the presence of the virus or infection of the disease. He found the plague bacillus in dust and scrapings from floors. In more than fifty per cent. of houses which have been regarded as uninfected rats inoculated with the dust from the floors immediately developed symptoms of plague and died. In milk inoculated with dust containing the plague bacillus a growth and multiplication took place. From one to two bacilli a field could be counted after one day's inoculation. The plague virus, in his opinion, does not spread through air or even through water unless it is excessively filthy, but most probably is putrid animal poison which falls to the ground and is taken into the human system mainly by inoculation.

SIR WILLIAM LOCKHART.

Before leaving India Sir William Lockhart, who has since arrived in England, issued a farewell order to the Tirah field force, in which he very truly and tersely stated that "never on any frontier expedition have the difficulties been more formidable, the punishment of the tribes more exemplary, or the submission more complete." As our readers are aware the border tribes, who are an eminently fighting, predatory race—Ishmaelites, their hand against every man—have borne no hatred or vindictive spirit, but having accepted their defeat and made their submission they were only too ready to become friends and even anxious to enter the military service of their late enemy. The tribes evidently admired the manly decision and straightforwardness of Sir William Lockhart, and he and Colonel Warburton, who was recalled from retirement to conduct the political negotiations in the Khyber, are to be warmly congratulated on the successful issue of a most difficult and laborious undertaking. Notwithstanding all that has been said we question whether any troops in the world could have done better on such an expedition, and certainly no Government could have been better served than was the Indian Government by the European and native armies and by the medical officers who accompanied them throughout the whole of the military operations.

THE LATE THUNDERSTORM AT DARJEELING.

In the terrific storm which occurred at Darjeeling on March 29th last the house of Surgeon-Major Moore at Jalapahar was struck by lightning and the occupants wery for a time rendered unconscious and some of them seriousle injured. Surgeon-Major Moore had a burn near one of his eyes and Mrs. Moore was partially paralysed for a time. Both are to be congratulated on their escape from more serious consequences. It fared worse, however, with a chuprassie who was rendered unconscious for some time and it is feared that the sight of one eye is lost. The dogs present in the house at the time were also struck and rendered insensible. The house itself has apparently received no damage.

CONTAGIOUS DISEASES IN THE STRAITS.

A letter has been received by the Straits Settlements Association from the Colonial Office, stating that Mr. Chamberlain is not prepared to sanction the re-enactment of the Contagious Diseases Ordinances in that colony, but he is conferring with the governor as to whether other measures can be taken to check the spread of venereal diseases.

ROYAL INSTITUTION. — On Friday evening, April 22nd, Mr. W. H. M. Christie, the Astronomer Royal, who made a journey to India for the purpose of observing the eclipse of the sun last January, gave a sketch of the work accomplished by Professor Turner and himself. It was originally intended that the Astronomer Royal's party should be stationed at Karad, a place near the sea-coast south of Bombay and Poona, but owing to the prevalence of plague the Indian Government transferred the party to Sahdol, a place lying far to the eastward, where the duration of totality was only 1 min. 45 sec. The lecture was copiously illustrated by views shown on the screen, the most remarkable of them being photographs of the solar corona as seen round the disc of the moon at totality.

Correspondence.

"Audi alteram partem."

ANTHRAX OR MALIGNANT PUSTULE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 1st, 1898, I was pleased to observe the report of two interesting cases of the above disease which occurred at St. Thomas's Hospital, under the care of Mr. H. Betham Robinson. What makes the matter more interesting is the fact that the disease is by no means an uncommon one in this colony. At times it is not only very prevalent, but very fatal, especially to those who contract the disease during the summer months of the year, when the thermometer ranges from 80° to 100° F. in the shade. I can readily confirm Mr. Robinson's opinion that early excision, in summer especially, is the only *sine quâ non* to a speedy cure and successful recovery. During my lengthy experience in the colony my services have been frequently called in to attend such cases, arising chiefly from inoculation from handling sheepskins and wool and hides of stock which have died of this malignant disease. The disease, too, in summer especially, is frequently produced by flies conveying the virulent virus from dead animals by inoculation through some pimple, cut, or abrasion of the skin. The face and neck, however, are the parts most commonly affected; next the hands and forearms. I have attended several cases occurring in the excessive heat of summer in which the patients have died within 12 or 14 hours after having contracted the poison or from the time they were first inoculated. The disease is characterised by symptoms of acute blood poisoning, usually in summer ending in early death. The poison may arise through the pulmonary or alimentary mucous membrane, but it is generally absorbed by inoculation through an abrasion, pimple, scratch, or cut of the skin through the handling of sheepskins, wool, or hides of dead animals. Animals which die from the disease should be buried or burnt and no person should be allowed to skin or make use of the wool or hides of the dead animal. In cases attacking the face and neck remedies seem to have little or no effect in arresting the progress of the disease, which spreads like wildfire. This discolouration and disfigurement from acute œdema increases most rapidly. It is undoubtedly in early stages when excision of the parts affected affords the best chance of a successful recovery. Not so, however, during the cool months of winter, for as a rule I have found topical applications, especially the ordinary "black wash," a most admirable and effectual remedy in such cases, assisted, of course, by tonics, especially quinine and a liberal diet. The disease first shows itself in the shape of a black pimple or dark-purple-looking slough or sore on the face, neck, or arm, varying from a simple pimple to the size of a shilling, covered with a darkish-coloured slough, accompanied by slight fever, lassitude, sickness, headache, and a dead, benumbed feeling at the sore. The dark-looking purple swelling or slough is a typical indication of the appearance of an anthrax pustule. The base of the pimple or pustule is somewhat swollen, red or purple, diffused, hard, and indurated. Before applying the "black wash" I generally freely scarify the sore and subcutaneous tissue, and within a week or ten days the symptoms abate with a complete disappearance of the disease. Such has been my experience in the treatment of a large number of cases which have occurred to my knowledge in this colony extending over thirty years. Those on the face and neck in summer are by far the most virulent and fatal and less evidently under the control of remedial agents unless seen and recognised at a very early stage and before the disease has made any progress. In one case, that of a man, aged forty years, who had been inoculated on the hand and arm from skinning sheep which had died from the disease, death took place within twenty hours. The patient came to me when the swelling had reached the shoulder. I suggested amputation but he declined, and within a few hours after he died from slight delirium and cardiac failure. He was a hawker or dealer in sheepskin but a most industrious, respected colonist. The second case was that of a woman, aged forty-two years, the wife of a shepherd; she had been inoculated on a scratch or pimple on the right cheek through

skinning a dead sheep. She died within twelve hours from the period of incubation in the middle of summer. The third patient was a man, aged fifty years, a herdsman, who had received inoculation on the neck under the lobe of the ear through handling a dead bullock—turning the carcass over in order to examine the brand. The matter at first was treated with contempt by the patient, but it proved fatal within fourteen hours from the time of inoculation during the excessive heat of summer. These were the only three cases which proved fatal; all the others made a successful recovery under tonic treatment, a liberal diet, black wash application, and free scarification of the sore. In the three deaths which occurred, from inoculation on the face and neck especially, the swelling and discolouration were something enormous, so much so that after death it was impossible to recognise the features, which more resembled a large block of charcoal than those of a human being. It is just as well that the history of these cases should appear side by side in your valuable journal with those which came under the observation of Mr. Robinson at St. Thomas's Hospital, if for no other reason than as a warning that the earlier the treatment the greater the probability of a satisfactory and successful recovery in such serious and most malignant cases.

I am, Sirs, yours faithfully,
ANDREW ROSS, M.D., M.P.

Molong, New South Wales, March 1st, 1898.

"COLLAPSE FOLLOWING LAPAROTOMY."

To the Editors of THE LANCET.

SIRS,—Would you kindly permit me to correct a misprint in my letter published in THE LANCET on April 23rd? I wrote that I injected "℥ ii. brandy" into the vein, not "3 oz." as printed.

I am, Sirs, yours faithfully,
CHARLES BOLTON, B.Sc., M.D., B.S. Lond.,
Senior Resident Medical Officer.

Evelina Hospital for Sick Children, Southwark Bridge-road, S.E., April 23rd, 1898.

*** We regret the error.—ED. L.

AN OBSERVATION REGARDING REVACCINATION.

To the Editors of THE LANCET.

SIRS,—Having read with interest the annotation entitled "The Need for Revaccination" in your last issue I should like to publish the following observation regarding revaccination. During the epidemic of small-pox at Gloucester, being called upon to revaccinate 60 young women the inmates of an "Anglican Home" at Malvern, I revaccinated 30 on the scars left by previous vaccination and the remainder on the normal skin, and found that the cases revaccinated on the old scars took more perfectly than those done on the normal skin. I also observed that in some of the latter cases, in addition to the reaction arising at the seat of the new abrasions, there was in several cases a sympathetic inflammatory action in one or more of the old scars. Calf lymph was used and there was not a failure in the 60 cases.

I am, Sirs, yours faithfully,
J. HOGGAN EWART, M.D. Edin.

Folkestone, April 25th, 1898.

"WHY CORONERS' INQUESTS ARE HELD."

To the Editors of THE LANCET.

SIRS,—Your annotation on "Why Coroners' Inquests are Held" leads me to call attention to the fact that the Registrar-General in his suggestions as to the filling up of certificates of the finding of the jury which are sent to the Registrar lays down the following principle: "The purposes to which inquests are intended to be subservient are partly legal, partly scientific and medical, and verdicts should therefore be such as to answer these several requirements." The question which arises is whether gentlemen who are Her Majesty's coroners are justified in neglecting the instructions of one of Her Majesty's departments of State. It appears to me that they are not.

I am, Sirs, yours faithfully,
LOVELL DRAGE.

Hatfield, April 23rd, 1898.

"AN UNKNOWN LARVAL PARASITE."

To the Editors of THE LANCET.

SIRS,—The following extract from the Medical Appendix by Dr. K. Ker Cross in Sir Harry Johnston's book on British Central Africa may interest your recent correspondents:—"*Ifwinjire*, not mentioned in any book; it is from the word *injira*, to enter. It is due to maggots in the tissues; native children suffer greatly; I have seen the whole side of a child riddled with holes. These maggots are common in dogs and antelopes." I am, Sirs, yours faithfully,
F. HYDE MABERLY, M.D. Dub.

Hardley-crescent, Earl's-court, S.W., April 24th, 1898.

THE ROYAL MASONIC BENEVOLENT INSTITUTION.

To the Editors of THE LANCET.

SIRS,—On looking through the list of candidates of the Royal Masonic Benevolent Institution for Widows of Freemasons I find that there are four belonging to our profession. I would throw out a suggestion to your readers who are Freemasons that in the future all medical votes should be given to candidates who are connected with the profession, thus ensuring their election and saving the wasting of votes by giving them away indiscriminately.

I am, Sirs, yours faithfully,
T. CAWLEY EAGER.

Woking, April 23rd, 1898.

"NEW DRUGS AND PREPARATIONS."

To the Editors of THE LANCET.

SIRS—May I be allowed to supplement Dr. Hooper's letter in THE LANCET of April 16th? While recognising that a chemist has no right to dictate to medical men what preparations they should use he must necessarily take a deep interest in making the knowledge of drugs as scientific and exact as possible and must therefore look with regret on the growing tendency to prescribe preparations of a more or less secret character. But if it really is necessary for the benefit of the public that such remedies should be prescribed it is surely not too much to ask that the maker's name and address should invariably be given. For example, Jones's liq. ergotæ or Robinson's syrupus sennæ may be well known in some provincial town, but it does not follow that their fame has reached the metropolis; or, again, elixir cascaræ "A. & H." may be clearly understood by every London chemist to refer to Allen and Hanburys' preparation, but it is quite probable that many a chemist in, say, Dublin or Glasgow might be considerably puzzled by such a prescription. As a matter of fact I have frequently, after sending for some such article to every likely wholesale house and well-known firm, found it necessary to write the prescriber for information as to maker's name and address; meanwhile, the patient has been kept waiting quite unnecessarily for two or three days and unjustly blames the unfortunate chemist, who is not only out of pocket by the transaction, but is blamed undeservedly for not keeping a better stock of drugs.

I am, Sirs, yours faithfully,
T. H. POWELL.

Denmark-hill, S.E., April 19th, 1898.

THE USE OF GLYCERINATED CALF LYMPH.

To the Editors of THE LANCET.

SIRS,—I thought that a quarter of a century ago the controlling power of a concurrent vaccination had been established beyond cavil. A late experience confirmed my acceptance of that teaching. I had to attend a little girl suffering from confluent small-pox and learned from her mother that both this and her other child, aged ten months, had been vaccinated unsuccessfully in early infancy—twice and once respectively. The family attendant had not insisted on more, for the mother had previously had small-pox and he too readily concluded that the children had inherited immunity. I vaccinated the infant, expressing my fear that it might already have caught the infection. This vaccination proved successful and the vesicles ran a perfectly normal course, though accompanied by a copious and exactly

synchronous eruption presenting all the characters of modified small-pox. The elder child died, but the infant recovered without a bad symptom. Mr. Collinson's letter in THE LANCET of April 9th impressed me deeply and painfully, but on reflection his cases seem to me to bear another interpretation and one of serious importance at the present juncture.

When the Stockwell Fever Hospital was first opened during the epidemic of 1870–71 for the reception of small-pox patients I acted as assistant medical officer for six months. Many hundreds were admitted during that period, but the only cases that showed evidence of recent vaccination were a series of four or five which all presented excellent cicatrices and had all been vaccinated by the same practitioner with lymph taken from revaccinations. They were the subject of a short paper in THE LANCET by the medical superintendent, the late Dr. J. B. Barbour, who took occasion to point out the worthlessness of this lymph, though the visible results of its inoculation counterfeited the genuine article. Mr. Collinson's cases seem on a par with the above and read in this light would constitute a grave indictment of the glycerinated calf lymph. A careful perusal of his startling list convinces me that all these vaccinations and revaccinations were impotent though "successful," and, indeed, his last quoted case, which he regards as anomalous, may, I think, be taken as the key to the series.

I am, Sirs, yours faithfully,

April 20th, 1898. WILLIAM MCLAURIN.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE REFORM OF THE ARMY MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I am directed to inform you that the enclosed letter has been sent by the President of the Royal College of Surgeons in Ireland to the Secretary of State for War.

I am, Sirs, yours faithfully,

ROBERT H. WOODS, F.R.C.S. Irel.,
Secretary of Council, Royal College of Surgeons in Ireland.

Dublin, April 26th, 1898.

[ENCLOSURE.]

Royal College of Surgeons in Ireland, Dublin, April 19th, 1898.

MY LORD MARQUIS,—In reference to the Army Medical Department and the reforms in it which are about to be carried out a rumour is current that it is intended to give no higher rank and title than that of colonel. I am unable, of course, to say what justification there may be for such a report, but as President of the Royal College of Surgeons in Ireland it is my duty to state that such a decision would create much disappointment. My College has loyally acceded to your lordship's request that I should nominate two civil surgeons to do duty in the present emergency. It was led to this by the sympathy which your lordship has expressed and by your manifest desire to remove the causes of discontent. But I am bound to say that I fear the dead-lock will continue if the ordinary accepted titles are not conferred upon the higher ranks of the service. It is almost unnecessary to repeat that the medical officers have never thought of commanding in the field, and that any suggestion of that sort is quite groundless. I beg your lordship to believe that in thus addressing you I only wish to help in speedily removing the difficulties which exist and which prevent the filling of vacancies in the Army Medical Department.

I have the honour to be, your Lordship's obedient servant.

W. THOMSON, President R.C.S. Irel.

To the Right Hon. the Marquis of Lansdowne, K.G.,
Secretary of State for War.

THE QUEEN REGENT OF SPAIN.

To the Editors of THE LANCET.

SIRS,—In the full and excellent account of the Ninth International Congress of Hygiene and Demography, published in THE LANCET of April 23rd, the paragraph relating to the reception of the members of the Congress at the Royal Palace at Madrid is of special interest just now. May I venture, therefore, to supplement your correspondent's notes by stating that the Queen Regent, whose wonderful courage and powers of head and heart are exciting the admiration of everyone, spoke most sympathetically and kindly of our sick and wounded soldiers and of the interest she took in the Queen's visit to them at Netley? Her Majesty also spoke of the work done by the nursing sisters in connexion with the plague in India and of the distress she felt in reading of the casualties amongst them. Indeed, it would be impossible to convey in words the infinite sympathy and tenderness with which she referred to our troubles in India and to everything connected with our sick and wounded invalids. I am, Sirs, yours faithfully,

W. G. MACPHERSON,
April 25th, 1898. Surgeon-Major, A.M.S.

THE DIPLOMA OF THE APOTHECARIES' SOCIETY.

To the Editors of THE LANCET.

SIRS,—With your permission I should like to make a few remarks respecting the late prosecution of a L.S.A. Lond. by the General Medical Council for describing himself as a physician and surgeon. I presume that the proceedings were taken under Sec. 40 of the Medical Act, 1858, for *wilfully and falsely pretending to be recognised by law as a physician and surgeon.* In 1888 the following letter was published in the leading medical journals:—

Society of Apothecaries, London,
Blackfriars, E.C., Sept. 27th, 1888.

MY DEAR SIR,—The title of Surgeon has long been in use, implying medical practitioner, but the L.S.A. is a licentiate in surgery as well as in medicine. It cannot be said that he is not a surgeon. It seems to me he may call himself what he likes—physician if he pleases.

Yours faithfully,

F. P. Moles, Esq. T. PEREGRINE, M.D., Secretary.

After such a statement, publicly made and never challenged, I cannot see that a L.S.A. who describes himself as a physician and surgeon can be said to *wilfully and falsely* misdescribe himself. I have in perfect good faith described myself as a surgeon for several years and I contend that we are recognised by law as such. Sec. 2 of the Medical Practitioners Act, 1876, says: "All legally qualified medical practitioners, with qualifications in medicine and surgery registered under 'the Medical Act,' shall be capable of being elected surgeons to county infirmaries or hospitals in Ireland."

The regulations for the admission of surgeons to the Army say with respect to the candidate: "He must possess two diplomas or licences, recognised by the General Medical Council—one to practise Medicine, and the other Surgery, and must be registered under the Medical Act in force in the United Kingdom at the time of his appointment. A candidate, however, who holds a single diploma from the Society of Apothecaries, obtained under the conditions of the Act of 1886, will be deemed to possess the double qualification required."

If these instances are not recognitions by law as surgeons, I should much like to know what constitutes legal recognition. It would be interesting to learn why the General Medical Council selected a practitioner in an obscure village for prosecution before a bench of magistrates none of whom have probably any special legal knowledge. If the Council in its newly awakened zeal is so anxious to prosecute the men who supply it with its funds, why does it not ride a tilt with some well-known and experienced practitioner? Dr. Major Greenwood, honorary secretary of the Brussels Medical Graduates' Association, barrister-at-law, has thrown down the gauntlet.[1] It must be confessed that the effect of these prosecutions on the public is anything but reassuring, leading them to believe that the L.S.A. is a sort of bogus diploma and its holder a false pretender and a cheat, who is to be hunted down by the General Medical Council, dragged into a police-court and fined, when he attempts to convey to the public a knowledge of the fact that he is a practitioner in medicine and surgery. Meanwhile any ignorant quack without a vestige of medical education may practise with impunity and the Council folds its hands and averts its eyes. I am, Sirs, yours faithfully,

April 18th, 1898. L.S.A. LOND., 1889.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Marked Decline of Mortality from Plague in Bombay.—Dissolution of the Plague Committee.—The Discoverer of Plague in Bombay.—Incidents in Plague Work.

THE past fortnight has seen a remarkably rapid decline in the death-rate for Bombay. Whereas it had reached 135 per 1000 it is now 95 per 1000. This decline is coincident with, but not necessarily dependent upon, the change of policy with regard to plague measures. There is now an almost entire absence of repressive measures, so that for all practical purposes the epidemic is taking its own course. This course, however, is an apparently natural one and does not appear to have been determined or even modified by

[1] Vide Brit. Med. Jour., April 9th, 1898, p. 990.

human agency. It has its parallel in last year's outbreak and it is also represented in both the primary outbreak and the recrudescence of the disease which have occurred in Poona. We may say that the epidemic will die a natural death, but we cannot so positively assert that the disease will suffer extinction.

The Bombay Plague Committee will be dissolved at the end of the month (April) and measures for dealing with the epidemic will be placed under a new organisation. Since the active work of the committee ceased and the native communities have been left to deal with the plague cases occurring in their several districts it is interesting to note that exactly the same proportion of unaccounted-for deaths occur now as formerly. About one-third of the excess mortality still continues to consist of unnotified plague cases. Even now 50 plague cases a day are unreported. It was imagined that under native management cases would not be secreted and that information of a larger proportion of cases would be forthcoming. The result has shown that the native population will not give information about their sick any more freely to their own leaders than they did in the days of military and other search parties.

When the history of the plague in Bombay comes to be written the name of Dr. Viegas must be duly acknowledged as its discoverer. This was a distinct omission in Mr. Birdwood's otherwise valuable lecture. Notwithstanding considerable opposition he forced the attention of the authorities to the calamity threatening Bombay, and by freely offering his cases for the criticism of his friends and opponents he was thus the means by which plague was officially recognised before the increased mortality drew general attention to the gravity of the situation. Sufficient credit has not been given to him for his professional acumen in discovering plague among his patients or for the energy with which he brought the danger home to the municipal authorities.

In view of the influx of people to Bombay with the present more hopeful view of the pestilence and to avoid overcrowding or the occupation of infected houses or of houses unfit for human habitation camp accommodation for about 17,000 people has been made available.

Plague has broken out at Kurrachee, but the cases at present are few in number and strenuous efforts are being made to prevent its spread.

The active measures adopted in other places than Bombay have led to disturbance and the lives of medical men and other officials have been placed in great danger. Surgeon-Captain Elphick was saved by his helmet from what would probably have been a fatal blow aimed at him during a disturbance at Jwalapur consequent on measures taken for removing a patient to hospital. Even in Bombay stone-throwing still continues to be practised occasionally at Europeans when moving about alone.

With the decline of the epidemic the type of the disease seems to be modified. The rate of mortality is lessening. Many comparatively mild cases are reported and amongst others two or three of the nurses engaged at the plague hospitals. A day's fever, with enlargement of one or more of the lymphatic glands, followed by debility for a week or longer, are the chief symptoms. Amongst the inoculated several instances of this modified form of the disease have been reported.

April 8th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Annual Congress of the Sanitary Institute.

As already stated in THE LANCET, the annual Congress of the Sanitary Institute is to be held in Birmingham next September. Already a local committee has been formed to make the necessary arrangements to receive the members in a manner worthy of this large centre. The Lord Mayor—Councillor Beale—has been appointed chairman, the executive committee and sub-committees have been formed, and a number of guarantors have given pledges sufficient to cover the expenses in case of need. Alderman Cook—the chairman of the Health Committee of the Town Council—is vice-chairman and the Lady Mayoress, who takes a great interest in the proceedings, has been appointed president of the conference on domestic hygiene. Sir Joseph Fayrer has accepted the post of President of the Congress. Other distinguished medical men and sanitarians have promised to be present and a meeting of much importance and interest is expected.

Habitual Inebriates.

At a meeting of the city magistrates held on April 21st a circular letter from the Lord Mayor of Manchester was read inviting support to the tenour of the following resolution recently passed by the Manchester Bench:—

That in the opinion of the justices of the city of Manchester here assembled it is of urgent importance that further provision be made by law for the restraint of habitual drunkards with a view to their reformation The justices, therefore, trust that the Government will in the forthcoming session of Parliament produce and pass the long-delayed Bill for this purpose, to which those concerned in the administration of justice look as the only hope of dealing properly with those criminal inebriates on whom the ordinary sentences have no effect.

Representations upon the same subject were read from the British Medical Association and the magistrates of Leeds. Some criticism followed upon details and the resolution was ultimately carried. A copy was ordered to be sent to the Home Secretary and to the Members of Parliament for the city. Some result of a beneficial kind is expected from the House of Commons' debate upon the question—certainly not before it is needed to deal with this much-vexed and difficult question.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Medical Guild.

THE report of the Medical Guild for 1897 shows that it is gradually becoming a powerful instrument for the abatement of various evil influences affecting the profession, whether they come as attacks from without or arise from misguided action on the part of the weaker brethren. The following subjects, among others, have been considered during the past year: Quack practice in various forms, medical aid associations, midwives, provident dispensaries, club and allied practices, consultations with "cheap doctors" (but as to this last it must be confessed that no conclusion was arrived at), a tariff of fees, unprofessional advertising, hospital reform, &c. With regard to one vexed question the following resolution was passed at the meeting on Nov. 5th last: "That the Council of the Medical Guild places on record its strong dissatisfaction with the present practice which obtains in the majority of the hospitals of Manchester and Salford of charging patients for services rendered, as, in its opinion, hospitals supported by voluntary contributions and which are charitable institutions ought not to exact such fees." The final clause of this resolution may perhaps remind one of what is called ungallantly a woman's reason, but it raises the question which underlies this practice—Are hospitals supported by voluntary contributions in the future to be charities? or are they to be places of business, where payment is made for services rendered? Are they to be institutions for the medical relief of the genuine poor? or are they to be in direct competition with the much suffering and, perhaps wisely, much complaining general practitioner? The guild can claim some success in restricting "the exploitation of the profession by medical aid societies promoted by interested laymen," and the council passed a resolution at one of the meetings strongly deprecating "the action of any medical man who, by giving such aid as permits of the intervention of any third party between medical practitioners and their patients, deals a severe blow at the best interests of the profession as a whole." This "intervention of any third party" is an impertinence which if submitted to is degrading to the medical profession and so destructive of the self-respect of each individual member of it thus interfered with that one cannot wonder, seeing how often it has been tolerated, at the light esteem in which the profession is held by those who so manipulate it for their own purposes. In accordance with English custom the members of the guild have had, not a dinner, but the ancient meal of supper together. It was a great success and "it is in accord with the principles of the guild to promote cordiality and good fellowship amongst the members." It is much to be wished for that the career of the guild should be prosperous, that its numbers and strength should rapidly increase, as it would become a most effective

agent for checking and thwarting the attacks, open and insidious, which our profession has continually to meet.

The Jubilee of Modern Spiritualism.

Demonstrations were held in St. James's Hall, Manchester, at the beginning of April to celebrate the jubilee of modern spiritualism, and were attended by a large number of the supporters of the Spiritualists' National Federation in Manchester and other parts of the country. Mrs. E. H. Britten of Manchester, described as "a notable apostle of spiritualism," opened a four days' jubilee bazaar and international fancy fair the object of which was to raise £2000—a very material agent—towards a propaganda fund "to promote the spread of spiritual knowledge and enable those who sit in the Valley of Shadow, in fear of death and the hereafter, to realise that man is a spirit, naturally immortal, progressive, and responsible; that there are no dead—all live, and under favourable conditions can communicate with their friends and loved ones, and help, guide, comfort, and bless them." On the platform there was a reproduction of the frame house at Hydesville, New York, where on March 31st, 1848, it is stated "that the spirits by 'raps' responded to questions and established a method of intercourse which has been adopted in all parts of the world." It is remarkable that the spirits in America—that ingenious and labour-saving land—should invent so clumsy a mode of sending messages from another world. Mrs. Britten declared, "after nearly forty years' experience ..... that it was the first scientific religion that the world had ever known and came from the source of all light—God our Heavenly Father—and from none other." She told how Victor Hugo had said to her again and again: "There is no more death; that which is called so is a splendid success," a remark characteristically French. During the afternoon a great tea-meeting was held, at which, it is said, about 2000 people attended, and this was followed by a mass meeting in the evening at which about 3000 people were present. The chairman, a Mr. Wallis, said that while fifty years since there were no spiritualists, in their sense of the word, to-day there were millions all over the world. Many addresses were given by apparently enthusiastic believers, and according to one gentleman much has been done by the movement, for it "had had to educate the Church and men of science and the general population as well." Possibly the general population is sadly ignorant of what has been done for it. But "most of all," as he said, "they had had to educate their own party and to develop their spiritualists out of the spiritualism that the angels brought to them from the spirit world." This was a task, and it is wonderful how Mr. Moore and his friends did it even with the help of the angels. Many of these people are no doubt sincere and belong to the so-called educated classes, but education does not necessarily confer wisdom or judgment in the sifting and weighing of evidence. It would be impolite to speak of "cranks," and yet there is an old saying "there's nothing so queer as folk."

Convalescent Pavilions at Ladywell Sanatorium.

A resolution was unanimously adopted at the meeting of the Salford Borough Council on April 6th in favour of erecting two convalescent pavilions on the land at Ladywell, one for scarlet fever patients with provision for 48 beds and the other for typhoid convalescents with 32 beds. The estimated cost of the new buildings will be £11,800.

April 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

St. Andrews University and Dundee College.

THE omens in connexion with the long-standing dispute between these two bodies at last appear to be favourable. At the recent meeting of the University General Council a much more reasonable and pacific tone prevailed and there is reason to believe that a practical scheme of agreement will soon be in operation. It is understood that the University Court has arranged to spend a considerable annual sum on the medical school at Dundee and that as soon as funds are available further chairs will be established there.

Glasgow University.

The classes for the summer session were opened on April 19th. The class of practical pathology is to be conducted by Professor Coats, who to the general gratification has returned from his Australian trip in restored health. The new Professor of Forensic Medicine has commenced his duties and he will also undertake the teaching of public health. Though no official action has been taken in connexion with the establishment of a chair in this last-mentioned subject the proposal has by no means lapsed and in the meantime laboratory work will be conducted under Professor Glaister's direction. The university court has reappointed Dr. Charles Workman to be an extra examiner in the subject of pathology for degrees in medicine and surgery. The court has adopted the report of the Universities Joint Committee in favour of action being taken to prevent any medical graduate using the name or title of his degree after his name has been removed from the Medical Register.

Glasgow Philosophical Society.

The meeting of this society held on April 20th, Dr. Ebenezer Duncan being in the chair, was occupied by a paper on the Bubonic Plague by Dr. Alexander Ferguson of the Western Infirmary Pathological Institute. Dr. Ferguson traced the history of the disease from outbreaks which occurred in Lybia, Syria, and Egypt in the third century B.C. and expressed the opinion that the present outbreak in Bombay was probably due to conveyance of the disease from Hong-Kong. The bacteriology of the disease was then discussed and a description given of the insanitary condition of the native quarters in Bombay; reference was also made to the various methods of serum treatment. The lecture was illustrated by lantern slides and microscopic demonstrations. At the same meeting Mr. Addison of the Deaf and Dumb Institute, Langside, read a paper on Deaf Mute Education, in which he advocated the establishment of a college for providing deaf mutes with opportunities for secondary and higher education and quoted in support the success of such an institution in America. Dr. Ebenezer Duncan also advocated Mr. Addison's suggestion.

Handsome Bequests to Glasgow Charities.

By the will of the late Mr. Adam Teacher a sum of £50,000 is left in trust to be divided among the infirmaries and other charities of the city. In addition, on the expiry of certain life interests, the further sum of £30,000 is to be divided between the Royal, Western, and Victoria Infirmaries.

Medical Appointments.

The Govan District Lunacy Board have, on the nomination of Dr. Watson, the superintendent, appointed Mr. Francis Odell Simpson, pathologist and senior assistant of the West Riding Asylum, Wakefield, to be senior assistant medical officer in the Hawkhead Asylum. Mr. Hugh Galt, M.B., B.Sc. Glasg., D.P.H. Camb., has been appointed Professor of Forensic Medicine and Lecturer on Public Health in St. Mungo's College, Glasgow, in succession to Professor Glaister, resigned.

(FROM OUR OWN CORRESPONDENTS.)

Important Verdict as to Medical Fees in Hospitals.

A RATHER important question as to the liability of hospital patients for medical fees was investigated by Mr. Justice Gibson and a special jury in the Nisi Prius Court, Dublin, on April 20th. Dr. J. J. Cranny, one of the surgical staff of Jervis-street Hospital, brought an action to recover £25, a fee alleged to be due to him by Mr. Thomas Lee, recently a patient in the institution, to which he had been brought with a compound fracture of his leg due to a street accident. It appeared that the defendant's leg was set by Dr. Cranny, who afterwards visited him at the hospital on thirty occasions and twice subsequently at his private residence. In support of his claim Dr. Cranny stated that it was the custom to charge medical fees to well-to-do patients in hospital. The defendant being a gentleman of considerable means he fixed 25 guineas as the amount of his fee. He had been sent a cheque for 5 guineas, which he returned. Mr. Meldon, the senior surgeon of the hospital, gave evidence as to the reasonableness of the amount claimed. The resident surgeon of the hospital, Mr. Caraher,

deposed that he was paid a salary and not allowed to accept money from the patients, while the visiting staff received no salary or other emolument except the students' fees. The secretary of the hospital, Mr. O'Brien, stated that there were no fees prescribed in either the public or private wards, but that people were supposed to pay according to their means. Dr. Cranny's patient occupied a private ward and acknowledged that a good cure had been effected in his case. For the defence it was alleged that Dr. Cranny attended the defendant, not at his request, but at the bidding of the governors of the hospital in his capacity as surgeon to the hospital and that the defendant by paying 3 guineas for treatment there had discharged all claims against him for medical attendance. The defendant stated, moreover, that the 5 guineas which he had offered to Dr. Cranny were given for the two visits which he had paid to him at his private house. He had been twice in the hospital and on each occasion before leaving gave £5 as a present to the hospital funds. No question as to medical fees was raised while he was there. Mr. Justice Gibson said the question, which he would leave to the jury, was whether Dr. Cranny rendered services on the terms that he was to be paid by the defendant. There should be, he thought, a set of rules in Dublin hospitals such as existed at St. Thomas's Hospital, London, where a man paid so much and received everything that he required. It appeared that in Jervis-street Hospital there was no formal rule. He trusted that in future when a hospital medical man intended to treat a patient as a private patient and charge him fees he would have an understanding on the point. The jury found that the plaintiff did not render the services on the terms that the defendant should pay especially therefor and judgment was accordingly entered for the defendant. The jury expressed their agreement with the judge that there was no reflection of any kind on Dr. Cranny for having brought the action as he did so honestly, believing himself to be acting rightly.

The Royal College of Physicians of Ireland and the Viceroy.

On the evening of April 23rd Sir George Duffey, the President of the Royal College of Physicians of Ireland, had the honour of entertaining at dinner at the College the Lord Lieutenant of Ireland, K.G., and a number of distinguished guests invited to meet his Excellency. The President occupied the chair. On his right sat the Lord Lieutenant, Lord Monck, Sir William Thomson, Sir William Kaye, Sir William Stokes, Sir William Kynsey, Dr. Grimshaw (the Registrar-General), Surgeon-Major-General Preston, Dr. Bull, and Dr. Beatty; on his left were Lord Ashbourne (the Lord Chancellor), Sir David Harrel, C.B., Sir Charles Cameron, Sir F. X. MacCabe, Sir Philip Smyly, Sir C. Nixon, Dr. Atthill, Mr. Swanzy, and Dr. J. W. Moore.

The Sanitary Congress, August, 1898.

The committee of the section of Preventive Medicine and Vital Statistics met on April 20th at the Offices of Public Health, Cork-hill. The chair was occupied by Sir George Duffey, the President of the Royal College of Physicians of Ireland, and subsequently by Dr. Grimshaw, the Registrar-General and president of the section.

Belfast Corporation (Hospitals) Bill.

The board of management of the Belfast Royal Hospital have been compelled, as they say, "with sincere regret," to notice certain statements which have been made in a petition of Roman Catholic ratepayers and inhabitants of Belfast in connexion with their opposition to the Bill promoted by the Belfast Corporation [1] to enable that body to grant a site to the proposed Royal Victoria Hospital. In the reply issued by the Royal Hospital authorities it is said that this regret is much increased by the fact that not only are several of these statements entirely destitute of foundation, but that they are calculated to excite sectarian prejudice against an institution the benefits of which have been always open to the sick of every creed and class with the most absolute impartiality and in which questions arising out of differences in creed, at all times exceedingly rare, have been for many years altogether unknown. Paragraphs 6 and 7 of the Roman Catholic petition contain the following statements: "Your petitioners will have no representation on the committee of management of the said hospital and no voice in the appointment of the managing, medical, surgical, or nursing staffs of the said hospital." "It is understood and believed that the new hospital is to take the place of the existing Royal Hospital. Your petitioners' co-religionists have been almost entirely excluded from the management and staffs of the hospital, and notwithstanding repeated remonstrances no provision has been made for ministering to the spiritual wants of Catholic inmates. Moreover, the Catholic poor requiring hospital accommodation very often found it impossible to obtain access to the wards of the Royal Hospital in consequence of the system of nomination for admission to the wards of the hospital which prevailed and still prevails." In their reply the Royal Hospital board of management say it is difficult to understand how assertions so entirely contrary to fact can have been seriously put forward. At no period did there exist any religious test or qualification for becoming a member of the general committee or of the board of management or of the medical and surgical staff of the Royal Hospital. According to the charter, everyone who subscribes £50 in one payment or £10 annually for six years becomes thereby a life governor and member of the board of management, and every subscriber of one guinea annually may be elected a member of the general committee and subsequently of the board of management. Of those qualified by payment of £50 8 are Roman Catholics; of those elected by the one guinea subscribers there are 3 Roman Catholics out of a total of 15, and of these one, an active and respected member of the board, is a Roman Catholic priest. From 1837 till the close of his valuable life the Right Rev. Dr. Denvir, Roman Catholic Bishop of Down and Connor, was one of the most influential and respected members of the board of management. From 1839 until the present time the medical and surgical staff have never been without one Roman Catholic member, commonly there have been 2, and occasionally 3. The relations of these gentlemen with their colleagues have been always of the most cordial and amicable nature. For many years a Roman Catholic surgeon filled the post of secretary and for the last nine years a member of the same church (Professor Cuming, M.D. R.U.I.) has been chosen by the suffrages of his colleagues to occupy the position of chairman of the staff. The principle of non-sectarianism has been carried out with the most scrupulous care in every detail of hospital management. No question as to his religious belief is ever addressed to any applicant for admission to the hospital, no illuminated texts or religious emblems are displayed on the walls, no public prayers are recited in the wards, there is no chapel within the building,—in fact, the hospital is managed as an institution with the primary object of the cure and relief of disease, while at the same time the committee has taken pains to give to the sick every facility for obtaining the aids and comforts of religion. The following notice is placed in the hands of every patient on admission: "If at any time while you are an inmate of this hospital you feel desirous of seeing a clergyman, on your communicating your wish to one of the medical staff, the house surgeon, or a resident pupil, the clergyman you name shall be sent for provided the visit is considered not injurious by the medical attendant." And further information on the same subject is given in a notice hung up in wards and passages. Every possible provision has been made for the convenience of clergymen called on to give the ministrations of religion to any of the inmates. The charge that the Roman Catholic poor found it very often impossible to obtain access to the wards of the Royal Hospital is sufficiently met by the fact that while it is impossible to state accurately the relative number of Roman Catholics who have been treated in hospital, as no inquiry is made regarding the religion of patients and there are consequently no records, it is the opinion of all those connected with the institution and who have the best opportunities of forming a judgment on the question that about one-half of the patients admitted to the wards are members of that Church, while their co-religionists probably do not amount to more than one-fourth of the population of the city of Belfast. It is most unfortunate that this sectarian dispute should have arisen about the new Royal Victoria Hospital, towards the building of which the inhabitants of Belfast so generously contributed over £100,000 as a memorial of the Jubilee of Her Gracious Majesty Queen Victoria.

[1] THE LANCET, April 16th, 1898, p. 1083.

April 25th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Rebuilding of the Academy of Medicine.

FOR a long time past the Academy of Medicine has held its meetings in a building which it is only allowed to use temporarily and which in addition is quite insufficient for the purpose. It is the old chapel attached to the buildings of the Charité Hospital and the hall used for meetings is on the ground floor, while the first and second floors are occupied by patients. There are no rooms or buildings which can be used for official work, for storing Transactions, for the library, or for any of the various departments which are under the care of the Academy—for instance, the vaccination department, the board in charge of prophylaxis and treatment of epidemic diseases, the board to which is entrusted the care of the various mineral springs, the sanitary and statistical departments, and the office for dealing with awards granted for sundry scientific researches. This state of matters, which has gone on for forty years, is the cause of continual complaints on the part of the Academicians — complaints all the more justified inasmuch as the Academy is the owner of a plot of ground near the Luxembourg on which it should long ago have erected the necessary buildings but which the State has utilised for the erection of some sheds serving as a temporary chemical laboratory for the Faculty of Sciences pending the building of the new Sorbonne. When this last is rebuilt the temporary buildings, instead of being pulled down and the site handed over to its rightful owner the Academy, are to be used as a new school of industrial chemistry, so that the State has been obliged to find another site for the Academy. That body wish that the new site should be fairly near the present one, so as not to cause unnecessary inconvenience to members. An understanding has been arrived at between the Government and the Academy for the purchase of a plot of ground in the Rue Bonaparte and a decree has just been voted by the Senate and the Chamber authorising the Education Minister to take the necessary steps. The total expense is estimated at 1,500,000 francs, of which the Academy will pay 540,000 francs by annual instalments according to the varying sums needed for the works.

The Learned Societies' Congress.

The annual meeting of the learned societies was held at the Sorbonne from April 12th to April 16th. This congress (originally organised by Durny with a view of being a centre for the reception of the work of the numerous provincial societies and so providing an annual stimulus to their zeal), of which the Minister of Education was president, concluded by a grand soirée held at the Ministry when a certain number of decorations were distributed. The section of the sciences of medicine and hygiene had some very interesting meetings and discussions. Among the papers read were the following:—On the Treatment of Pulmonary Tuberculosis by means of Ichthyol (Professor Combemale), on Infant Feeding (Dr. Lobet), on Tuberculosis in the Army (M. Decaux), and on Suicide among Children (M. Moreau).

The Resection of the Sympathetic.

Messrs. Combemale and Gaudier of Lille showed a patient before the Academy of Medicine at the meeting of April 19th. The patient was the subject of exophthalmic goitre and she had been operated on by undergoing resection of the sympathetic. The results were as follows: first, a most important diminution of exophthalmos; secondly, lowering of the beats of the heart from 200 to 100 in the course of a week while at the same time the painful phenomena in the præcordia disappeared; and, thirdly, there was no marked effect upon the goitre itself. Messrs. Combemale and Gaudier concluded from their observations that in cases of exophthalmic goitre when the tachycardia is intense and continuous, when this is the only symptom, or when there is also exopthalmos, there is always the risk of dangerous symptoms supervening. In such cases section of the cervical sympathetic, which acts most probably by preventing the hypersecretion of the thyroid gland, is the best operation to do. At the same meeting M. Jonnesco read a paper on the Cervical Sympathetic in Epilepsy and glaucoma. He has performed this operation forty-six times. In epilepsy out of 35 cases, some unilateral and others bilateral, 15 had been kept under observation for from nine to eighteen months; 9 were cured completely and no untoward effects had been observed. In exophthalmic goitre total and bilateral resection had always been done. Four operations had been performed from fifteen to twenty months ago, and recovery was perfect in all. The tachycardia disappeared fairly quickly, the goitre got smaller and harder, and as for the exophthalmos it disappeared almost at once. In 6 cases of glaucoma the results were very valuable. When the glaucoma was simple and chronic the results were excellent; the sight improved and the pain disappeared. In one case where glaucoma had appeared after the goitre, bilateral and total resection had acted upon both these affections and a cure was the result. With regard to irritative glaucoma the results were much less satisfactory. Vision did not improve, although the tension in the eyeball became much less. Resection of the cervical sympathetic is, then, in the case of some patients a good operation and gives good results in a number of diverse diseases.

The Invariable Presence of Pneumococci on the Surface of the Tonsil.

On April 15th MM. Bezançon and Griffon laid before the Hospitals Medical Society the results of some researches which they had made on the presence of the pneumococcus on the surface of the tonsil. In place of using inoculations *en masse*, after the method of Netter, they employed a culture medium specially fitted for the pneumococcus—namely, the serum of a young rabbit. It is generally admitted that the pneumococcus can be found in the throats of healthy individuals about once in five times, but according to MM. Bezançon and Griffon this is a wrong proportion and due to faulty technique in the examination. The pneumococcus may exist constantly as a saprophyte in the same way as the streptococcus. If up to now the pneumococcus has not been found in more than a fifth of the cases examined it is easily explained by an alteration in the method of cultivation, the method of culture being for choice by taking some of the tonsillar mucus and not simply the saliva. The forty individuals whom MM. Bezançon and Griffon examined were of varying ages and kinds—quite young children, adults, old men, some taken from a hospital atmosphere, some from laboratories, and some living under circumstances from which any source of contamination could be reasonably excluded. In none of these patients was there any history of pneumonia. The only conclusion which can be drawn from these facts is that this organism is found in a great variety of diseases.

The Military Hospital at Nice.

The President of the Republic has just been taking a few days' rest at Nice. During his stay there M. Faure made a thorough examination of the military hospital and inquired into the matter of the everlasting negotiations which have been going on with the municipality. More than thirty-five years ago the garrison of Nice requested an increase in the hospital which had been originally founded under the Italian *régime*. However, the sanitary service is to-day very nearly in the same condition as it was in 1860 The garrison then numbered 1100 men but now numbers 6000. There are no means for isolating infectious or suspicious cases and the regimental surgeons are compelled to treat a portion of their patients in the infirmary. The President has promised to use all his influence to put an end to this state of things, owing to which the good name of the French sanitary military service has with some reason been discredited.

April 26th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The English-speaking Practitioner in Italy.

IN the following circular addressed to the prefects throughout the kingdom by the Under-Secretary of State for the Home Department may be recognised the death-knell of the Santini Bill, which had for its object to exclude from practice in Italy all English-speaking medical men not provided with an Italian diploma. I give the circular textually: "I have ground for believing that not in every instance nor in every quarter is respect paid to the

regulations which, in terms of the 'Legge Sanitaria' now in force (Art. 23), apply to foreign physicians and surgeons professionally engaged in the kingdom. To this, therefore, I recall the attention of your worships, begging you kindly to exert a prompt and effective surveillance to the end that, except in special cases for which those physicians and surgeons are expressly summoned from abroad, the said practitioners, if they have not obtained the diploma of Italy, should restrict themselves to vouchsafing professional assistance to foreigners only. I shall feel obliged by your graciously acknowledging this circular.—Signed (for His Excellency the Minister of the Interior), ARCOLEO." Considering that English-speaking practitioners never court an Italian *clientèle*, for the reason (among others) that the low scale of remuneration makes it not worth their while, considering, moreover, that they only ask to be allowed to practise among their compatriots without let or hindrance, we must hold this circular, issued by authority of Government, as giving official and final sanction to the *status quo*, all attempts to modify which (in the sense of the Santini Bill particularly) being discountenanced and therefore to be abandoned. The Di Rudini Government may be congratulated on this decisive step which, let us hope, none of its successors will be ill-advised enough to reverse. One significant clause in the circular cannot have escaped your readers' notice—that, to wit, in which it is conceded that in special cases foreign consultants not possessing the Italian diploma may be called to Italy to give professional advice to non-compatriots, Italian or other. This has to my knowledge been a practice by no means rare. Just ten years ago, when the late Emperor of Brazil was confined to bed in Milan and under the treatment of his body-physician assisted by Professor Semmola of Naples, the supervening cerebral complications led to Professor Charcot being summoned from Paris and with the best results. This happy intervention, however, the Santini Bill would have made irregular and illegal. Now we have it on authority of Government that it is quite a legitimate proceeding and that on the occurrence of a parallel case it may be open to the patient's family and professional advisers to reinforce Italian opinion by that of another school, not only French or Austrian or German, but British or American or colonial.

The Government Inquiry into the Foundling Hospitals.

The "incredible scandals" of which these institutions—particularly in the Neapolitan and Venetian provinces—have been the source or centre are well known to readers of THE LANCET[1] which has also noted from time to time the steps taken to put a stop to them and to introduce a more humane order of things. The "Commissione Reale d'Inchiesta"—medical in its presiding head (Dr. Tommasi-Crudeli) and largely medical in its composition—has been for several months employed in verifying those "scandals" and lately held at the Home Office a plenary sitting to take note of the work already done and that remaining to do. Its chief business was to consider the report of Dr. Raseri, who had been commissioned to collect and summarise the returns of the medical men told off to inspect the provincial foundling hospitals. This duty Dr. Raseri and his subordinates were found to have discharged with thoroughness and effect, whereupon the "Commissione" decided to proceed to inspect on the spot those institutions which Dr. Raseri had indicated as exceptionally bad in their administration and thereafter those which had a fairer record to show. The first localities to be visited turn out to be those already indicated by THE LANCET as offering the grossest abuses in foundling management, and these are Naples and some other cities of the south, and Padua, Venice, Vicenza, and Rovigo in the north. The last-named city will receive peculiar attention as having initiated reforms at once bold, humanitarian, and economical, diminishing the mortality while reinforcing the surveillance, and all this at less outlay than hitherto considered possible. As I have said, the "Commissione" is largely medical in its *personnel* and for the new departure it is taking will command the services of Dr. Celli (Professor of Hygiene in the Roman School) for the south, and of the Senator Tommasi-Crudeli (the well-known pathologist) for the north.

April 23rd.

[1] THE LANCET, June 12th, July 10th, and Oct. 2nd, 1897.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Kasr el Aini Hospital and Medical School.

AT the beginning of 1884 Mr. Clifford Lloyd among his reforms at the Ministry of the Interior, separated the Government Hospital from the School of Medicine and placed the hospital under the direction of Mr. H. Milton. Under his management the building and its inhabitants have been thoroughly reorganised, so that the hospital will in many respects bear favourable comparison with any in Europe. This reform has been a slow growth of many years' zealous toil and reflects the greatest credit upon Mr. Milton. But the school, divided from the hospital only by a paling, has never made the same strides towards a European ideal. Three energetic Englishmen have done their best to leaven the lump of Egyptian inertia, but the teaching language has been Arabic, and it has for years been known that the teaching staff was unfit for modern requirements. One example of this archaism will suffice. The professor of surgery is a man who has done very good work in his time, but his methods in the wards and his systematic lectures are not based on asepticism. Lately, too, the school curriculum has been extended to six years, examinations have been made more severe, and, unfortunately, the initial pay offered to the Government sanitary officer has been reduced to £72 a year. For these reasons, among others, the medical school has ceased to be popular with parents and pupils and it became quite necessary to make some reform. Several times the suggested study of the question had to make way for more pressing needs, such as cholera, the Soudan, and threatened plague, but last October Dr. Perry, superintendent of Guy's Hospital, was invited by the Egyptian Government to report to them in Cairo on the school and hospital. He wrote out a carefully prepared scheme for their future guidance, and this scheme was for five months under the deliberation of various officials of the Government. Now, with a few modifications, it has been passed by the Council of Ministers and will come into effect in October next. The school course has been reduced to four years but a fifth post-graduate year will be open to those who wish for extended study. This fifth year will be compatible with resident hospital appointments and will count as the first year of service for those who elect to enter the Government employ. The school and hospital are to be merged into closer relationship than heretofore and one head is to direct both with the aid of a school committee and a hospital committee chosen from the staff. The director is debarred from private practice and from professional work in the hospital and is to reside within the precincts. Dr. Keatinge has been selected as the first director. A few native teachers will be superannuated, and preliminary scientific subjects will be omitted from the course. Five or six new appointments will be filled by Englishmen, including two resident posts worth about £240 a year, with rooms but without board. The visiting physicians and surgeons, with, of course, right to private practice, will be paid at the rate of £400 and £320 a year. The details of these vacancies have not yet been fixed by the Government, but they will shortly be advertised in the medical press.

Institut Egyptien

Exactly a hundred years ago Napoleon created an Egyptian Institute for discussing scientific questions relating to this country. Several papers bearing on medicine and sanitation were read by well-known army doctors such as Desgenettes, Bruant, Savaresi, and Larrey. Eventually the Institute decayed and was revived by French influence, since when it has been a French stronghold from which all but a few Egyptians and Italians were excluded. For some years there has been but one English member and he was only elected after being blackballed three times. But now a compliment has just been paid to the English medical men in Egypt by the unsolicited election of Dr. Sandwith to a vacancy among the forty.

British Wounded in the Soudan.

Written despatches from the Atbara have not yet reached Cairo, but we know by telegram that the wounded are doing as well as can reasonably be expected under antiseptic care in a hot, dry climate. The following particulars of the

wounds received by soldiers in the storming of Mahmoud's entrenchments on April 8th show that the firing must have been directed low—perhaps after several volleys fired over the heads of the attacking party. Head, 1 severe, 1 slight wound; chest and stomach, 3 severe, 4 slight; hand and arm, 4 severe, 10 slight; shoulder and back, 2 severe, 3 slight; thigh, 3 severe, 3 slight; knee, 7 severe, 1 slight; leg and ankle, 18 severe, 6 slight; not specified, 16; total, 82 wounded. All the wounds in the British brigade were from rifle-bullets, with the exception of two slight spear-wounds, and to-day a telegram has come to say that all the bullets have been extracted. The wounded are now at Genenetti, on the Nile, about twenty miles north of Berber. Thence the new railway will carry them to Wady Halfa, where they will be shipped by steamers to Assouan. The slightly wounded will then travel by post boat to Luxor and thence by train to Cairo, while for the severe and dangerous cases Messrs. Cook's steamer *Mena* is being fitted up as a hospital ship to bring them by river from Assouan to Cairo, under charge of Surgeon-Captain O'Callaghan.

Medical Officers.

The following officers are now with the British troops at the front:—Brigade-Surgeon-Lieutenant-Colonel Macnamara as principal medical officer; Surgeon-Major Robinson, Surgeon-Major Smythe, Surgeon-Major Stuart, Surgeon-Major Braddell, Surgeon-Major Carr, Surgeon-Major Adamson, and Surgeon-Major Mathias; Surgeon-Captain Marder, Surgeon-Captain Reilly, and Surgeon-Captain Borradaile; Surgeon-Lieutenant Bliss, Surgeon-Lieutenant Cummins, and Surgeon-Lieutenant Hopkins. Nearly all the senior officers were fortunate enough to be at the fight of April 8th. It is now fully believed that there will be no more fighting until the Nile rises, and the army generally is anxiously expecting a few weeks' leave.

Cairo, April 13th.

Obituary.

HENRY MARSHALL, M.D. EDIN., F.R.C.S. EDIN., F.R.S. EDIN., M.R.C.S. ENG.,

CONSULTING SURGEON TO THE BRISTOL GENERAL HOSPITAL.

AFTER a short illness Dr. Henry Marshall died at his residence, Caledonia-place, Clifton, on April 24th, the cause of death being pneumonia following influenza. Dr. Marshall, whose father was for many years vicar of Christ Church, Clifton, was born at Edinburgh in 1833 and received his medical education at Edinburgh University, where he graduated M.D. in 1855. Four years later he obtained the F.R.C.S. Edin., having taken the M.R.C.S. Eng. in 1854. After holding resident appointments at the Edinburgh Royal Infirmary Dr. Marshall commenced practice in Bristol and was appointed surgeon to the Bristol General Hospital. Having practised as a surgeon in Bristol for about ten years he severed his connexion with the hospital, except that he was appointed consulting surgeon to the institution, and henceforth practised as a physician. He was also for some years lecturer on medical jurisprudence at the Bristol Medical School. The deceased was F.R.S. Edin. and a past-president of the Bath and Bristol branch of the British Medical Association. Dr. Marshall on one occasion became involved in litigation through having, with another medical practitioner, signed a certificate of lunacy in the case of a woman, who brought an action which was tried at the Bristol assizes. A verdict was returned in favour of both defendants and members of the profession raised a subscription to show their sympathy and to defray the costs of the action. Dr. Marshall was a zealous Churchman and was for many years president of the local branch of the English Church Union. Sympathetic allusions were made to his death by the Bishop and the Dean of Bristol in their sermons on April 24th. The deceased, who was one of the best known medical practitioners of Clifton, was extremely popular and highly respected and much sympathy is felt for the widow and children.

ROBERT HENRY SCANES SPICER, M.D. ST. AND.

THE death is announced at the age of seventy years of Dr. Spicer of North Molton, Devon. He was the only son of the late Robert Spicer of Exeter and obtained his professional education at the Middlesex Hospital. After taking the diploma of M.R.C.S. Eng. in 1855 he at once returned to his native county to North Molton where he practised for forty-three years. He was at work to the last, only the day before his death setting a fractured leg. He passed away after a few hours' suffering from cardiac failure, of which, however, he had had previous warnings. He had always taken the keenest interest in the welfare of the parish and its inhabitants and many a young fellow in both hemispheres owes his start in life and his present good position to the recommendation, advice, and assistance of Dr. Spicer. He was a man of wide general information and culture and was, moreover, an enthusiastic and accomplished sportsman of the old school, to which belonged his friends Parson Jack Russell, Mr. Froude Bellew, and the Rev. John Matthews. Popular and respected by persons of all ranks and opinions in North Devon he has gone to his rest amidst tokens of widespread regret, leaving five children to lament their loss and to cherish his memory.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Jules Worms, principal medical officer of the Northern of France Railway and a well-known authority on hygienic subjects. He was born in 1830 in Alsace and studied medicine in Strasburg. He was in the early part of his professional career anatomical assistant in the Military Medical School of Val-de-Grâce and subsequently served as surgeon in the Crimean War. His investigations on the spread of diphtheria and cholera were well known and he was the author of various articles in Dechambre's Dictionary of Medicine. His reading was especially wide and he frequently brought the advances in surgery and gynæcology made in Germany and English-speaking countries under the notice of his medical brethren in France.—Dr. G. Dragendorff, formerly Professor of Pharmacognosis in the University of Dorpat. He died at Rostock, his native place, where he had been living for several years and where he took his degree of Doctor of Philosophy, for he was not a medical man but a pharmacist. In 1862 he went to St. Petersburg as editor of the publications of the Pharmaceutical Society and director of its laboratory, in which capacity he had to occupy himself to a considerable extent with forensic medicine. In 1864 he was appointed to the chair of Pharmacy and to the charge of the Pharmaceutical Laboratory at Dorpat, or Iurieff as it is now called, where he remained until his resignation four years ago. He published a great number of works on medicinal plants.

THE NINTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY.[1]

(FROM OUR SPECIAL CORRESPONDENT.)

HEALTH AT SCHOOL.

ON considering the resolutions which were read out at the final meeting and before the whole Congress it is impossible to avoid a feeling of surprise at their weakness both in bulk and in quality. For instance, one of the best attended sections of the Congress was that dealing with infancy and school life. Here the debates were long and arduous, yet but little was brought forward at the general meeting as resulting from these debates. There was the resolution in favour of the short holiday colonies which I have already described, another demanding that all accouchements should be managed according to the principles of antiseptics, and from the seventh section, which dealt with the question of exercise at school, there were some platitudes to the effect that outdoor exercise was the best form of exercise especially for early childhood and that gymnastics or other special forms of muscular effort which are employed to correct malformations, &c., should be treated as therapeutics rather than as exercise in the ordinary sense of the word. Though there was thus such a poor outcome so far as practical resolutions are concerned, some

[1] Previous reports of the proceedings at the Congress were published in THE LANCET of April 16th and 23rd, 1898.

good papers had been read. The fact is that the Spaniards, who naturally formed the majority in all the sections, have very vague ideas as to the methods of working a congress by means of resolutions. Indeed, the word "resolution" in this sense does not seem to be known to them and the word "conclusion" is used instead, which again is sometimes confused with the word "theme." Thus instead of a pithy resolution consisting of but a few words we were sometimes treated to three or four pages of lengthy dissertations. It was like voting in favour of a pamphlet instead of a resolution. Yet Miss Mercedes Zella worded her conclusions in a practical manner, dividing them under numbered headings: Thus (1) that all school books should be printed in clear, large type; (2) that the paper should not be transparent; (3) that children's eyes should not be strained and that they should not be compelled to stoop over their books; (4) that the lines should not be more than eight centimetres in length, &c. These points, though adopted in the section, were not presented at the general meeting.

STERILISED MILK AND REDUCED INFANT MORTALITY.

One of the most carefully prepared papers read in this section was presented by M. Clement Gény, administrator of the school funds, the *crêches*, and the school colonies of the First Arrondissement of Paris. He showed that the number of children, aged under one year, dying in Paris amounted to 10,000 in 1886; and, in spite of the increase of population, to only 7665 in 1895. The average for the seven first years in this period was 8850, that for the last three years 7573, which is equal to a gain of 14·4 per cent., and this would be higher still if the increase of population were taken into account. In 1886, of the children under one year of age, 364·5 died per 1000; in 1895 the proportion per 1000 was 254·2. The reduction in the death-rate is especially marked in respect to diseases of the digestive organs and with regard to zymotic diseases. There has also been a notable reduction in the number of infants who have died from syphilis, the annual average of deaths from the latter disease being 232 up to 1892 and only 143·5 since that date. But in the same lapse of time the deaths from tuberculosis have increased. M. Gény considers that the more general practice of sterilising the milk given to infants has largely contributed to bring about these good results. This was only done in rare instances previously to the year 1893; but at about that date the utility of such precautions began to be appreciated by the public at large. M. Gény also showed that the proportion of infants who die from diseases of the digestive organs is much greater among those who are fed from the bottle, but that this proportion has been reduced by the abolition of the tubes, the introduction of better bottles, and of sterilised milk. He therefore concluded that the great saving of infant life realised in Paris since the year 1893 is due: (1) to the hygienic measures taken by the city of Paris to prevent the spread of infectious diseases, notifications, disinfections, &c.; (2) to the treatment of diphtheria by the antitoxin serum of Behring and Roux; and (3) to the more general use of sterilised milk and improved feeding bottles. The employment also of the *couveuse* has rendered great service, as formerly 66 per cent. of the children weighing at birth less than two kilogrammes died, whereas now with the aid of infant incubators the greater number are saved. M. Gény therefore urged that hospitals, charitable institutions, and poor relief authorities should provide themselves with incubators so as to help to save the children of the poor.

AN INTERNATIONAL BACTERIOLOGICAL COMMISSION.

The first section, dealing with Bacteriology, passed some important resolutions, which were read out and confirmed at the final general meeting. One resolution was to the effect that an international bacteriological commission should be elected. The names of seven German and six French bacteriologists were suggested, together with those of Dr. Woodhead and Dr. Allan Macfadyen for England. One or two names were mentioned for most of the other nationalities. Then Dr. Janowski, Chief of the Medical Service at the Hospital of the Infant Jesus at Warsaw, proposed a resolution to the effect that there should be a standard definition of diphtheritic antitoxin in all places where serum is produced. On the proposal of Dr. Chantemesse of the Pasteur Institute it was decided that the International Bacteriological Commission should study this matter and report to the next Congress with a view of indicating a method by which antitoxin could be rendered of uniform strength in all countries. Further, the Commission should prepare a report on the question of the harmlessness of anti-diphtherial serum when used in cases of laryngitis and other minor affections. The Commission was also requested to deal with the dangers resulting from the local antiseptic treatment of diphtheria. The section unanimously recognised that such treatment favoured secondary consequences and deprived the organism of its principal means of defence against the malady.

TUBERCULOSIS.

Referring to the Bacteriological Section I should mention an important paper which was read concerning Tuberculosis. At Geneva Dr. Georges Perron commenced some experiments which he continued at Valencia, where Dr. Amelio Gimeno, the general secretary of the Congress, took the matter up energetically. Dr. Jean Torres Babi also joined in the work and the paper was presented in the name of these three gentlemen. They obtained serum from donkeys and with this serum rendered guinea-pigs immune against tuberculosis. The first experiments gave every promise of success. When they applied the serum to human beings they obtained good results for external tuberculosis of the knee and other parts and for lupus. Their patients seemed to be cured. But when dealing with tuberculosis of the lungs the result was very different. Microscopic examination had revealed the presence of the Koch bacillus, but the patients had no fever, no night sweats, and no yellowish-green sputa. Treated with the serum their general health at first seemed to improve and the number of the Koch bacilli decreased in notable proportions. On the other hand, the streptococcus and staphylococcus pyogenes increased. In two cases the last sputa examined showed that the Koch bacilli had entirely disappeared; but with the disappearance of the specific bacillus of tuberculosis hectic fever set in, and one patient died in eight and the other in ten days with the symptoms of septic poisoning. In consequence of these experiences the writers of the paper conclude that tuberculosis and pulmonary phthisis are two absolutely distinct diseases. Tuberculosis is due to the Koch microbe and can be cured by the serum they have prepared. The second is a consequence and after result of the first, due not only to the bacillus of tuberculosis, but also to the streptococcus and the staphylococcus. No remedy has yet been found for this latter development of the disease; it is characterised by hectic fever, nocturnal perspiration, purulent expectoration and cachexia. The experiments made seem to indicate that there is antagonism between the different agents of phthisis and that it is at least dangerous to attack one of these agents without simultaneously destroying the others. Therefore to treat tuberculous phthisis it would be necessary to obtain serum from a donkey which had been rendered immune, not only against the Koch bacillus, but also against the streptococcus and the staphylococcus found in the sputa of phthisical patients. The serum they have prepared from a donkey could be used when dealing only with the Koch bacillus, as, for instance, in the case of children born from phthisical parents, when it could be employed as a preventative.

GEOGRAPHY AND SOCIAL ASPECT OF TUBERCULOSIS.

In the third section, dealing with Climatology, the question of Tuberculosis also came up for discussion. Dr. Albert Palmberg of Finland presided and read a statistical paper on the Geographical Distribution of Phthisis in that country. He did not think the cold was in itself a cause of increased mortality because the Laplanders and those who lived furthest to the north suffered less, but in winter patients could not obtain as much fresh air and out-of-door exercise; also the beneficent effect of sunlight was less felt. In Finland the most fatal months were March and April, when the temperature was relatively high; but at that time, as the contrast between indoor and outdoor temperature decreased, there was less ventilation through the body of the walls and the smaller fires caused less draught.

Dr. Ph. Hauser of Madrid had also a very interesting historical paper on Tuberculosis, from which he concluded that the problem was not only a medical but also a social question. A crusade should be organised against the sputa of phthisical patients. The pathogenic germs were present in all large aggregations of human beings and the disease was one of the consequences of economic and social evolution. The remedy was the improvement of the physical, moral, and intellectual well-being of the population. The disease was the consequence of human degeneration by which the weak were swept away

to make room for the strong. Though infectious it only infected the weak. It may be cured if the patient can be placed under conditions which favour the re-establishment of the equilibrium between his organic forces; and as in the struggle for existence this is often impossible it becomes quite as much an economical or social as a medical question. Section III. finally carried the following resolutions:—

1. The danger of tuberculosis is sufficiently urgent to necessitate legislative intervention.
2. To succeed in this respect we must complete our knowledge as to the causes of propagation or contagion.
3. All nations should study the geography of tuberculosis as the best means of acquiring the necessary knowledge of the subject. To avoid errors this study should be extended over a period of twenty years.
4. The struggle against tuberculosis should be a subject of discussion in all congresses and such discussions should be continued till the disease is finally eradicated.

OLD CLOTHES AND HAIRDRESSERS.

With regard to the prophylaxis of infectious diseases generally a resolution proposed by Dr. F. Ovilo was carried unanimously in the second section and confirmed at the general meeting. The resolution was worded as follows:—

Firstly, old clothes are often a certain vehicle for the transmission of such serious diseases as tuberculosis, diphtheria, small-pox, scarlet fever, &c. The sale of old clothes should be forbidden unless they have been disinfected.

Secondly, the utensils and implements used by hairdressers are often the cause of skin diseases and other more serious complaints such as lupus and syphilis. Each person should use his own scissors, &c., and the authorities should seek by all possible means to induce hairdressers to employ rational means of disinfection. In no case should the master hairdressers be allowed to compel their assistants to attend to the hair of persons bearing evident signs of disease that are known even by the profane (*sic*) public.

URBAN SANITATION.

The discussion which had been anticipated with regard to the drainage of Paris did not take place. Of the two delegates appointed by the Parisian house proprietors' syndicate one only reached Madrid. Evidently he felt that there was a strong majority against him, for he did not venture to raise the question at issue. Consequently the section on Urban Sanitation was able to carry the following resolutions, which were also approved by the general and final meeting:—

1. Public health is ameliorated and the outbreak of epidemics prevented in towns and dwellings by the immediate removal of all fermentable matter and by an abundant distribution of water.
2. The pavement of the streets should be smooth and as impermeable as possible, so as to be easily cleaned and so as to prevent the contamination of the subsoil.
3. Special measures should be taken in the construction of houses, so as to protect the walls and the entire building from damp and from subsoil emanations.
4. The drains within the houses ought to be so constructed and laid as to prevent any stagnation and to secure a rapid flow to the street sewer of soil and slop water. The drain-pipes must be water-tight and air tight, perfectly constructed and ventilated and provided with syphon traps to protect the interior of the dwelling from all sewer air.
5. The public sewers should assure the rapid flow of sewage, so that there shall be no stagnation till the outfall has been reached. The sewers must be thoroughly ventilated.
6. The width of the streets must be as great as possible and in proportion to the height of the houses. This proportion should be established in all localities taking into consideration local and climatic circumstances. The light should have free access to the innermost parts of inhabited dwellings and there should be windows on at least two sides of the building.
7. Special regulations or by-laws should be made in each locality by the public authorities so as to render the practical application of the above principles obligatory. The Government and the municipalities should resolutely seek to realise these principles and more especially those that relate to the interior of dwellings.

THE MILITARY AND NAVAL SECTION.

The Military and Naval Section does not seem to have passed any resolutions, but there were some very interesting debates. The French officers present produced a great impression when they explained that the prevalence of typhoid fever had been reduced in the ranks of the army and the general health of garrison towns improved by prohibiting resort to *cafés* and dram-shops, where the water employed was not above suspicion. The soldiers were ordered not to enter these places and the tradesmen soon found it to their advantage to improve their water-supply.

THE BRITISH SECTION AND THE PERMANENT COMMITTEE.

The Permanent Committee, which was appointed according to the resolution carried at the London Congress, 1891, consists of 29 members, of whom 3 are English, for the division of Hygiene, and of 15, of whom 1 is English, for the division of Demography. Of these 44 members only 10 were present at Madrid and all the 4 British representatives were absent. Fortunately the Permanent Committee may fill up vacancies and may appoint assistant members during a session of the Congress. Consequently the 10 members of the Permanent Committee invited more than 30 of the delegates to assist at the meeting which was to be held early on the Thursday morning. Surgeon-Major Macpherson, delegate of the War Office, and Dr. MacAlister, were requested to be present on behalf of the British Section. It was generally felt that though the Permanent Committee had the legal right to select these gentlemen, still they would hold a much stronger position if their appointment was confirmed by the British Section. Mr. Adolphe Smith, having secured the approval of a few other British members of the Congress, took the initiative of convoking a meeting of the British Section. After a good deal of canvassing this meeting was held at the Hotel de la Paix on the Wednesday after the reception at the Court. 17 British delegates were present and 7 were absent. Dr. MacAlister was voted to the chair. As the members of the Permanent Committee were elected for two congresses at Budapest it was supposed that their mandate would be exhausted at the end of the Madrid Congress. Therefore the British Section thought itself entitled to suggest names for the next Permanent Committee. A good deal was said about figure-heads who did no work and about the mismanagement of the British Section on the present occasion, together with the failure to obtain information and the promised reduction on railway fares. Some delegates, however, testified to the promptitude and courtesy with which Dr. Corfield had answered their letters of inquiry. Others declared that the only information they had obtained was from the columns of THE LANCET. Several prominent names were suggested for the Permanent Committee, and objections were made that, however eminent in the realms of science, these gentlemen had no special experience of international congresses nor were they likely to be able to devote much time to explaining to intending members how they were to obtain rooms and travel at reduced rates, &c. But it was generally agreed that when the next Congress was near at hand a sub-committee or organising national committee would have to be appointed to look after the interests of the British members of the forthcoming Congress. On this understanding the following names were approved unanimously: Lord Lister, Dr. Vivian Poore, Sir Richard Thorne, and Dr. J. Tatham, with the names of Professor Lane Notter of Netley and Dr. Corfield as alternatives if any of the above gentlemen declined to act. The meeting was then about to adjourn, but Mr. Adolphe Smith protested that it was absolutely indispensable to give the British representatives some instructions as to how to act at the meeting of the Permanent Committee to be held on the morrow. He explained that the Congress had of late lost much of its influence because it failed to act in a collective capacity; that as the next Congress would probably meet at Paris an effort would be made to revert to the earlier and better methods of organisation; and he concluded by urging that the British representatives should support such an attempt. This suggestion was approved and the meeting adjourned.

THE PERMANENT COMMITTEE AND THE NEXT CONGRESS.

Forty-seven invitations to attend the Permanent Committee were issued and 40 of the persons who were invited attended. Invitations to hold the next congress at Lisbon and at Brussels were received, but these were withdrawn in favour of Paris during the great Exhibition of 1900. It was then decided that the International Medical Congress and the International Congress of Hygiene should be held in succession one after the other, so that some, at least, of the medical men attending might be present at both congresses. Further, it was resolved to ask the Medical Congress to transfer its section of hygiene to the Congress of Hygiene. With regard to the latter congress the opinion was expressed that the number of sections should be considerably reduced and that, apart from the opening and closing ceremonies, there should be plenary sittings of the entire Congress at which scientific subjects would be discussed. The Permanent Committee confessed that it had failed to revise the resolutions to be submitted to the present Congress but promised to do so in future. A mistake had been made with regard to the election of the Permanent Committee, for though appointed at Budapest it did not sit at Budapest and the two congresses placed under its direction were those of Madrid and the forthcoming congress to be held at Paris. Nevertheless, it was generally felt that the Permanent Committee required to

be strengthened and therefore it was decided to appoint an executive committee which was to act when any emergency occurred. This executive committee was to consist of all the general secretaries of all previous congresses, therefore of experienced congressists, and consequently Dr. Vivian Poore, as the general secretary of the London Congress, represents Great Britain on the executive committee. This committee has the power to appoint three or four persons experienced in the management of congresses. Perhaps we have here, at last, a body technically capable of acting.

A WORD IN PRAISE OF OUR HOSTS.

Looking upon the Congress as a whole I think I may safely assert that it has come to the vast majority of the foreign members as an agreeable surprise. It was not supposed that Spain would do so well, especially in the present critical political situation. The Spaniards are not a business people; they have but little sense of the value of time and these national defects naturally made themselves felt in matters of detail during the Congress. These shortcomings were, however, more amusing than mischievous. For instance, after an excellent dinner given by one of the learned bodies of Madrid the foreign guests present were really more pleased at having the *menu* served to them with the cheese than if it had been forthcoming at the proper time, as this accident supplied the pretext for a little good-humoured merriment. Of the various entertainments and receptions given I have already spoken at some length, but I have not mentioned that the foreign military and naval surgeons were greatly impressed and delighted with the banquet and welcome given to them by their medical colleagues of the Spanish army and navy. It is especially in the social relations established during the Congress that the foreign members have most reason to congratulate themselves on having come to Spain. After all, it is exceedingly pleasant to be in a country where everyone knows how to behave like a gentleman, from the beggar in the streets to the grandee standing on the steps of the Throne. This is all the more welcome as a contrast to the manners displayed by the young students and others who were admitted to the Congress at Budapest. At the Madrid town-hall and elsewhere there undoubtedly was a crush at the buffets, but there were no unseemly scenes. The crush was due to the fact that there were more guests than the building could hold and whenever a foreign delegate made himself known the Spaniards standing in front of him always either made room or tried to pass to him what he wanted. A Spaniard would die a thousand deaths rather than compromise his dignity. A beggar in Spain will refuse relief if it is not given politely. Spain is lacking in the energy, the enterprise, and the capacity for hard work which characterise the virile population of Hungary; but the Spaniards are a race of gentlemen, and this is a very great advantage, especially when so delicate a matter as an international congress has to be taken in hand. Consequently the foreign members carry away with them a very favourable impression of the Madrid Congress. They were, I repeat, most agreeably surprised. If Spain is as ready and able to face the United States of America in war as she has proved herself able, contrary to the anticipations of many, to carry out the work of peace which the Congress came to achieve, the Americans are likely to experience surprises as disagreeable as those of the Congress were agreeable.

TORBAY HOSPITAL RECREATION GROUND.—The land acquired by Torquay as a Jubilee memorial of the Queen's reign was on April 14th formally presented to the governors of the Torbay Hospital by Mr. Rockhey, the ex-mayor, and has been converted into a recreation ground for the use of the patients and staff. The outlay in connexion with the scheme was about £1700.

PRESENTATIONS TO MEDICAL MEN.—On the occasion of the presentation of certificates to the successful members of the Pinxton Collieries Ambulance Class on April 17th, Mr. T. Corkery, M.D. Irel., of Alfreton, the instructor to the class, was the recipient of a silver vegetable dish as a thank-offering for his First Aid instructions.—Dr. Connor, superintendent of the Glasgow Medical Mission, has been presented by the workers and friends associated with him with a number of surgical books and instruments as a practical recognition of his services during the past twelve years.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In April the following candidates passed in the subjects indicated:—

Surgery.—J. Buckley (Section II.), Manchester; F. W. Chesnaye (Section I.), St. George's Hospital; A. E. Freer, St. Mary's Hospital; F. Hasler (Section I.), London Hospital; T. C. Last, St. George's Hospital; F. A. Leete (Section I.), Royal Free Hospital; G. M. F. Pereira, Calcutta and Royal Free Hospital; J. M. Sanderson, Cambridge and London Hospital; and T. B. Sellors, Middlesex Hospital.

Medicine.—J. Buckley (Section II.), Manchester; E. R. R. Cheesman, Charing-cross Hospital; W. A. Clement, Bombay; J. L. Elliott, Leeds; S. R. Hallam, St. Thomas's Hospital; F. Hasler (Section I.), London Hospital; H. W. Hues, Birmingham; E. J. Trevor-Jones, St. Thomas's Hospital; F. A. Leete (Section I.) and Miss Pantin (Section II.), Royal Free Hospital; O. T. A. Phillips, Cardiff and London Hospital; and J. M. Sanderson, London Hospital.

Forensic Medicine.—E. R. R. Cheesman, Charing-cross Hospital; W. A. Clement, Bombay; J. L. Elliott, Leeds; S. R. Hallam, St. Thomas's Hospital; F. Hasler, London Hospital; H. W. Hues, Birmingham; M. Jenkins, Guy's Hospital; J. Jones, Edinburgh and London Hospital; F. A. Leete, Royal Free Hospital; O. T. A. Phillips, Cardiff and London Hospital; and W. R. Wilson, Dublin and Belfast.

Midwifery.—J. Brown and J. Buckley, Manchester; P. Cator, St. Bartholomew's Hospital; H. E. Dalby, Charing-cross Hospital; J. L. Elliott, Leeds; S. R. Hallam, St. Thomas's Hospital; W. St. G. G. Hill, St. Mary's Hospital; B. Hogan, London Hospital; H. W. Hues, Birmingham; O. T. A. Phillips, Cardiff and London Hospital; R. C. Robertson, Charing-cross Hospital; J. M. Sanderson, London Hospital; T. B. Sellors and O. C. Sibley, Middlesex Hospital; N. Walmisley, St. Bartholomew's Hospital; A. J. Watson, St. Mary's Hospital; and W. R. Wilson, Dublin and Belfast.

The diploma of the Society was granted to the following candidates: Messrs. J. Buckley, W. A. Clement, S. R. Hallam, B. Hogan, M. Jenkins, T. C. Last, T. B. Sellors, and E. J. Trevor Jones, and Miss Pereira.

UNIVERSITY OF DURHAM.—At the first Examination for the degree of Bachelor in Medicine, held at the College of Medicine, Newcastle-upon-Tyne, in April, the following candidates satisfied the examiners:—

OLD REGULATIONS.

1. *Chemistry with Chemical Physics, and Botany with Medical Botany.*—William Purton Allen Hardwicke, College of Medicine, Newcastle-upon-Tyne.
2. *Chemistry with Chemical Physics.*—Francis Bernard Henry Caudwell, M.R.C.S., L.R.C.P., Charing Cross Hospital; Herbert William Dudgeon, M.R.C.S., L.R.C.P., Guy's Hospital; and Richard Denington Fisher, M.R.C.S., L.R.C.P., London Hospital.
3. *Elementary Anatomy.*—William Ernest North Smith, College of Medicine, Newcastle-upon-Tyne.

NEW REGULATIONS.

1. *Elementary Anatomy and Biology, Chemistry, and Physics.*—*Second Class Honours:* Harry Jessop, Mason College, Birmingham. *Pass List:* Katharine Mary Helen Hawkins, London School of Medicine for Women; and Kenred Mason, Leonard Montgomery Markham, Leonard Clark Newton, Robert William Nevin, and Frederick Charles Ramsbottom, College of Medicine, Newcastle-upon-Tyne.
2. *Chemistry and Physics.*—Alice Maud Dodd and Ida Emilie Fox, London School of Medicine for Women; Henry Wallace Furnivall, University College Hospital, London; James Alfred Giles, College of Medicine, Newcastle-upon-Tyne; Ivon Henry Skipwith Hawes, St. George's Hospital; Florence Dyer Durell Ledgard, London School of Medicine for Women; and Edward Henry Milner-Moore, St. Mary's Hospital.
3. *Elementary Anatomy and Biology.*—Thomas Engelhart Amyot, College of Medicine, Newcastle-upon-Tyne; Anthony Bourchier Bradford, St. Thomas's Hospital; Clement Harlow Cox, Mason College, Birmingham; Marshall Haver and Ernest Edward Norman, College of Medicine, Newcastle-upon-Tyne; Thomas Eben Pemberton, Mason College, Birmingham; Ralph Stuart Renton, College of Medicine, Newcastle-upon-Tyne; Gayton Warwick Smith, Guy's Hospital; and Basil Edward Spurgin, College of Medicine, Newcastle-upon-Tyne.
4. *Elementary Anatomy, Chemistry, and Physics.*—George Ernest Froggatt, Middlesex Hospital; Alfred Ernest Gisburn, College of Medicine, Newcastle-upon-Tyne; Philip Arthur Hendley, King's College, London; Vincent Blumhardt Neafield, St. Mary's Hospital; and Godfrey de Bec Turke, King's College, London.
5. *Elementary Anatomy.*—Charles Ravenscroft Stewart, St. George's Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Heidelberg:* Dr. Gottlieb has been promoted to the chair of Pharmacology, in succession to the late Dr. W. von Schroeder.—*Madrid:* Dr. Don Antonio Alonzo Cortés of Valladolid has been appointed to the Professorship of General Pathology, in succession to the late Dr. Letamendi.—*Montpellier:* Dr. Baumel has been appointed to the Clinical Professorship of Children's Diseases and will be the first occupant of the chair.—*Rome:* Dr. Giacomo Rem-Picci and Dr. Ferruccio Schupfer have been recognised as *privat-docenten* of Medical Pathology, Dr. Tullio Rossi-Doria as *privat-docent* of Midwifery and Gynæcology, Dr. Saverio Santori

as *privat-docent* of Hygiene, and Dr. Paolo Casciani as *privat-docent* of Medical Hydrology. — *Parma:* Dr. Camillo Lodigiani has been recognised as *privat-docent* of Surgical Pathology and Operative Medicine, and Dr. Serafino Patellina as *privat-docent* of Midwifery and Gynæcology.—*Turin:* Dr. Alberto Benedicenti has been recognised as *privat-docent* of Experimental Pharmacology.—*Vienna:* Dr. Emil Schwartz has been recognised as *privat-docent* of Internal Medicine.

MEDICAL MAGISTRATES. — Mr. F. H. Woods, L.R.C.P. Edin., M.R.C.S. Eng., J.P., of Uralla, and Mr. J. Baldwin Meredith, L.R.C.P., L.R.C.S. Edin. L.F.P.S. Glasg., J.P., of Raymond-terrace, have been appointed members of the Licensing Court for the licensing districts of Uralla and Raymond-terrace, New South Wales respectively.

A SEQUEL TO THE SKIN-GRAFTING CASE AT AUCKLAND.—At a meeting of the Auckland Charitable Aid Board an application from Dr. A. C. Purchas (defendant in the skin-grafting case which was reported by our New Zealand correspondent in THE LANCET of April 23rd), under date March 5th, for three months' leave of absence as honorary surgeon of the District Hospital was declined, and it was agreed to declare the office vacant and to call for applications for the position. In this connexion Mr. Baldwin wrote a memorandum to the secretary of the board stating that he had not received any official notification that Dr. Purchas had left the colony and as it was his week of duty he would be glad to know what arrangements were to be made for the care of his patients. It was unanimously resolved that should Dr. Purchas again apply for appointment to the honorary staff he should be asked to explain why he did not comply with the hospital regulations which provide that he should have arranged with the medical superintendent for the care of his patients when about to leave the hospital.

FACTORY GIRLS' COUNTRY HOLIDAY FUND.—The annual meeting of subscribers to this fund was held at the Mansion House on April 22nd. The Lord Mayor presided and said that during the past year 1250 girls had been sent into the country for 2120 weeks at a cost of £1230, of which he was glad to see that £246 were paid by themselves. Princess Christian had consented to become patroness in place of the late Duchess of Teck, who gave the fund her valuable support in the earliest and most difficult stage of its existence. He urged that one of the most satisfactory features of the work was that those who were sent away for a holiday contributed whenever possible to the expense and that therefore while they were helped they were not pauperised. Mrs. Garrett Anderson urged the immense importance of the country holiday to the girls and the pleasant and helpful recollections it provided them with all the year round. Mrs. Arnold White said that this was not a question of charity but of national importance. The factory girls were penned up in our great cities, shut out from all the health-giving delights of nature, and yet they were to be the mothers of the future. This crowding into the great cities was really deteriorating the fibre of the nation; the monotony of toil was part of the pathos of the city. Canon Newbolt, Miss Yeatman, Mr. Barton Kent (Master of the Skinners' Company), and Mr. W. G. Rawlinson also appealed most earnestly for increased support for the fund. The honorary secretary is Miss Canney, St. Peter's Rectory, Saffron-hill, London, E.C.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, APRIL 21ST.

The Food and Drugs Bill.

MR. CHAPLIN, replying to Mr. Channing, said he would introduce the Bill to amend the Food and Drugs Act as soon as he saw any prospect of making progress with the measure.

Imported Milk.

Major Rasch asked the President of the Local Government Board whether his attention had been called to the resolution passed by the Central Chamber on April 5th with reference to the importation of chemically treated French milk and whether he proposed to take any steps to exclude it.—Mr. Chaplin replied that his attention had been called to this resolution, but the Local Government Board had no power to prohibit the importation of milk into this country or any other article of food or drink and he had not at present evidence which would justify him in taking such action even if it were in his power.

Poisoning at Gosport.

Major Rasch asked the Financial Secretary to the War Office whether his attention had been called to the poisoning of certain soldiers by vinegar said to have been adulterated with arsenic at Gosport and whether he could say if the article was of foreign manufacture, and if not if he would give the name of the contractor.—Mr. Powell Williams replied that the inquiry which had taken place had shown that a further investigation was desirable, and he did not think it advisable at the present moment to make any detailed statement on the subject.

Prosser's Well at Maidstone.

Mr. Henry J. Wilson asked the Secretary to the Treasury, in view of the fact that the chemical officers of the Inland Revenue were appointed referees in disputed cases of adulteration under the Sale of Food and Drugs Act and that water was specially excluded from the operation of that Act under Clause 3, would he state whether it was in any way the duty of the chemical officers to undertake the analysis of water for sanitary purposes and act as referees in disputed cases; and under what authority the chemical officers of the Inland Revenue recently analysed the water taken from a well at Maidstone known as Prosser's Well and in their report expressed the opinion that the water was not liable to contamination; whether, as a consequence of such report, the application to the court to close the well was refused; was he aware that this well was in close proximity to houses in which no less than 14 cases of enteric fever occurred during the recent epidemic; and whether, seeing that the report was not signed by the chief of the laboratory, the action of these chemical officers was sanctioned by the responsible authority.—Mr. Hanbury said that under section 70 of the Public Health Act, 38 and 39 Vict. cap. 56 the magistrates were empowered if they saw fit to cause water of which complaint was made to be analysed at the cost of the local authority. In cases of difficulty the magistrates occasionally asked for the assistance of the Government laboratory and it had been the practice for many years when such assistance was asked for by the court to undertake an analysis of water. In the present instance the Justices at Maidstone requested the assistance of the Government laboratory and it was given in accordance with the usual practice. With regard to the latter part of the question he understood that evidence as to the possibility of danger arising from the local surroundings of the well was given before the court by the medical officer of health and that the magistrates on consideration of all the evidence before them decided to refuse the application. The action of the laboratory officers was not specially sanctioned by the Board of Inland Revenue in this particular instance, but those officers undertook the analysis at the request of the magistrates in accordance with a practice which had for years existed with the approval of the board.

Venereal Disease in the Indian Army.

Mr. James Stuart asked the Secretary of State for India whether he had received a memorial, signed by 79 registered medical women practising in the United Kingdom and in India, protesting against the measures recently enacted for dealing with venereal diseases in the Indian Army; and whether he would lay this memorial upon the table of the House in continuation of the Parliamentary Paper, East India Accounts and Papers, Memorials, and Representations, C. 8495, 415 and C. 8402 of last session.—Lord George Hamilton replied that he had received the memorial and it would shortly be presented to Parliament.

The Institute of Preventive Medicine.

Mr. MacNeill asked the Home Secretary whether he was prepared to grant a licence for the practice of experiments on the bodies of living animals to the new Institute of Preventive Medicine on the Thames-embankment at Chelsea; whether he was aware that a large building, called the animal house, was in course of construction at this institute, where the victims of vivisection experiments were to be kept while awaiting operation and in various stages of their sufferings, and that a crematorium was also in course of construction for the burning of the bodies of animals when destroyed by the vivisectors' experiments; whether he was aware that the Chelsea guardians had passed a resolution deprecating the granting of this licence and that a number of the occupants of the flats on the Embankment had protested against the establishment of this institute in the locality and had given notice to their landlords that they would leave their flats the moment it was established; and whether, having regard to the fact that a petition with 183,607 signatures was presented to the right honourable gentleman deprecating on behalf of the inhabitants of Chelsea the practice of vivisection in their midst, he would withhold his assent to the licensed practice of vivisection in Chelsea.—Sir M. White Ridley replied: I have already stated in this House that after full consideration of every aspect of the question and of representations to which the hon. Member refers I have not thought it possible to refuse the transfer of the registration of the Institute from the present buildings to the new premises in Grosvenor-road. I have satisfied myself that the arrangements at the new premises are perfectly suitable for the purposes for which they are registered. Of course, no painful experiments can be made there until the person wishing to perform them has been properly licensed to do so.

The Supply of Calf Lymph.

Mr. Chaplin, in reply to Mr. Pickersgill, stated that no arrangement had been made, or was proposed to be made, with the British Institute of Preventive Medicine for the preparation or supply by them of calf lymph. The arrangement made was for the hire by the Local Government Board of certain rooms at the Institute for the use of officers of the department in connexion with the preparation or supply of calf lymph by the Board.

The Powers of Vaccination Officers.

Mr. Broadhurst asked the President of the Local Government Board whether, in the case of relieving officers who are also vaccination officers, he intended that they should act in vaccination cases without the authority of the Poor-law guardians or even against their authority, and if so whether legislation would be necessary to provide this new power and if not under what Act the power was given.—Mr. Chaplin said, in reply, that he contemplated that relieving officers who were

vaccination officers should be in the same position in this matter as other vaccination officers and that vaccination officers should undertake prosecutions independently of any directions from the guardians themselves. No new legislation would be required. The vaccination officer would exercise these powers under the Vaccination Acts of 1867 and 1871 and under regulations issued by the Local Government Board under the provisions of the Act of 1874.

The Budget.

There was little of special interest to medical men in the Budget statement made at this sitting of the House by the Chancellor of the Exchequer. Sir Michael Hicks-Beach told the usual story of an increase in the revenue from beer and spirits and tobacco and he was able also to point to a great accession of popularity to the article of cocoa. In the way of concession to the taxpayer he announced his attention to make an abatement of £150 in incomes between £400 and £500, of £120 in incomes between £500 and £600, and of £70 in incomes between £600 and £700. These abatements refer to the amount upon which income-tax is charged.

FRIDAY, APRIL 22ND.

The Dum-Dum Bullet.

Mr. Davitt asked the Under Secretary of State for War whether his attention had been directed to the statements, attributed to Dr. von Brums, in a paper on "Inhuman Weapons of War," read a few days ago at the German Surgical Congress, to the effect that the Dum-Dum bullets used by British troops in the North-West frontier of India produced fearful results on the human body, and that Germany should try to obtain a condemnation from the European Powers of the further use of such bullets; whether any steps would be taken to meet these views; and whether he would forbid the sale of these bullets by British makers to the belligerents in the Spanish-American war.—Mr. Powell Williams said that he had no knowledge of the statements referred to or of the paper mentioned. He thought the general ideas as to the effect of the Dum-Dum bullet were very much exaggerated. It was nothing like so severe as that of bullets which had been previously employed.—Mr. Dillon asked whether the opinions of medical men had been taken by the War Office.—Mr. Powell Williams replied that the English medical officers of the army had been shown the results of the use of this bullet and they were of the opinion indicated in his answer.

Lead Poisoning in the Potteries.

Mr. Coghill asked the Home Secretary whether, to prevent the serious evils arising from the use of lead in the manufacture of china and earthenware, he would appoint a small committee of scientific experts to ascertain if it was possible to use a glaze which would be entirely free from lead in its composition.—Sir Matthew White Ridley replied that he was taking steps to secure the services of two eminent scientific experts to test and report on the various glazes, but it must be clearly understood that the inquiry could deal only with the question of the comparative danger or safety of different materials. The further question how far materials found to be harmless or relatively harmless lent themselves to the practical requirements of each section of the trade was one for the manufacturers to decide by experiment. He felt sure he might count on their coöperation in this matter and their readiness to adopt satisfactory substitutes, if such should be found, for the dangerous glazes now in use.

Prison Medical Officers.

Sir M. White Ridley, in answer to Mr. Pickersgill, said that in England and Wales there were ten local and five convict prisons which had a medical officer who was required to devote the whole of his time to the service.

Vaccination Prosecutions.

Mr. Labouchere asked the President of the Local Government Board whether all prosecutions for non-compliance with the obligations of the Vaccination Act had until now been instituted by boards of guardians; whether it was intended in future that they should be instituted by the medical officer of health, with or without the approval of the board of guardians, under directions from the Local Government Board; and whether the cost of such prosecutions would be a charge on the rates.—Mr. Chaplin replied that it had been the practice of the vaccination officers to institute proceedings under the Vaccination Acts either under general or special directions of the guardians, but he was not prepared to say that it had invariably been the case. There was nothing in these Acts which made it necessary that the guardians should give directions for or approve of these proceedings. It was not proposed that the proceedings should be instituted by the medical officers of health but by the vaccination officers who were under the statute appointed for the express purpose of prosecuting persons charged with offences against the Vaccination Acts or otherwise enforcing their provisions. The cost of prosecutions would be charged on the rates as at present. In reply to a further question Mr. Chaplin said that if vaccination officers refused to fulfil the duties for which they were appointed it would be the business of the Local Government Board to interfere.

The Plague and the Mecca Pilgrimage.

Sir Walter Foster asked whether, in view of the reappearance of plague in Jeddah this year, Her Majesty's Government intended to take any steps to stop the pilgrimage to Mecca from British possessions and from Egypt.—Mr. Balfour replied: It has been found unnecessary to take steps to prohibit the pilgrimage, so far as British Indian subjects are concerned, as the Government of India reports by telegraph that no more Indian pilgrims will leave India for the Hedjaz this season. As regards Malay pilgrims it was decided, when the first outbreak of plague at Jeddah was notified, that it was already too late to prohibit the pilgrimage, as all intending pilgrims for this year's Haj had already left the Straits Settlements. With reference to Egypt the question is one which directly concerns the Egyptian Government, but Her Majesty's Agent and Consul-General at Cairo reports that intending pilgrims have been warned of the danger from plague and informed that those who persist in going in face of this warning will be required to sign a declaration that they will not return to Egypt until the complete disappearance of the plague, and steps have been taken to prevent such return.

MONDAY, APRIL 25TH.

The Treatment of Inebriates.

The Home Secretary introduced and explained the Bill of the Government for the treatment of inebriates. The principal object of the measure, he said, was to substitute for the present penal treatment in prisons of habitual drunkards who rendered themselves amenable to the criminal law—called in the Bill criminal habitual drunkards—a reformatory treatment which should be undergone in institutions specially organised and established for the purpose. These buildings were referred to in the Bill as inebriate reformatories and might either be established by the State—called in the Bill State inebriate reformatories—or by county or borough authorities or private individuals—called in the Bill certified inebriate reformatories. The step now proposed to be taken had already been taken in several foreign countries, and in this country, besides being urged by many local authorities, had in particular been recommended by three recent departmental committees, the Home Office Committee on the Treatment of Inebriates in 1893, the Prisons Committee in 1895, and the Scotch Committee on Habitual Offenders in 1895. Two classes of criminal habitual drunkards were recognised in the Bill. There was first the class of offenders who were guilty of serious crime into which they had been drawn by habits of drunkenness. There was, secondly, the class of petty offenders who appeared continually before the summary courts charged with some one or other of the offences specified in Schedule 1 of the Bill. In their case the drunkenness was the crime or the greater part of it. The first class was deal with in Clause 1, the second in Clause 2. Power was given in both cases to commit to inebriate reformatories under certain conditions and safeguards. These conditions in the first case were that the offender must have been found guilty on indictment of the offence actually charged against him and that the fact of habitual drunkenness, unless admitted by him, must have also been found by the jury. In the second case the conditions were that the offender must be charged with one of the offences specified in Schedule 1 after three convictions of such offences within the previous twelve months, and that unless he consented to his case being disposed of summarily the matter should be tried by a jury. In these cases a committal would only be possible if the jury found both the fact that he had been so previously convicted and the fact that he was an habitual drunkard. The Bill proposed that as a general rule, to which the court would be able to make exceptions if other reformatories were willing to receive them, habitual drunkards of the first class should remain as at present under the complete control of the State and that any period of reformatory treatment to which they might be sentenced should be passed in one of the state reformatories, for which, however, there would be special regulations laid down by the Secretary of State. The second class would be treated in the certified reformatories. These reformatories would require a certificate from the Secretary of State, they would have to conform to the regulations as to management, classification, treatment, employment, &c., which by the Bill the Secretary of State was empowered to make, and they would be subject to inspection by the State. Provision was also made for a contribution from Imperial funds towards the expense of maintaining these institutions. In these respects the analogy of the Reformatory Schools Acts had to some degree been followed. The establishment of these reformatories was not made compulsory upon local authorities. In the case of both classes provision was made for allowing persons committed to reformatories to be released on licence. The second part of the Bill made some improvement in the existing Acts which dealt practically with non-criminal drunkards only. These Acts had not been largely operative and the committees he had alluded to, who made inquiry as to the reason, attributed the fact to the difficulties in the way of admission and readmission into the retreats, the shortness of the *maximum* period of detention allowed, the want of power to require the inmates to engage in healthy occupations, &c. Provision was accordingly made in the Bill to extend the *maximum* period of detention to which a patient might agree to submit himself to two years; to simplify, without weakening the safeguards against abuse, the procedure as regards admission and readmission; and to enable rules to be made regulating among other things the treatment and employment of patients. The Bill extended to England and Scotland, but he would be quite prepared to consider the question of its extension to Ireland.

TUESDAY, APRIL 26TH.

The Troops and Civilian Practitioners.

Colonel Welby asked the Under Secretary of State for War whether he was aware that at stations in the United Kingdom troops and those belonging to troops were in medical charge of civilian practitioners; and whether he could see his way to employing in their stead Army Medical Officers retired on a pension or gratuity, where no additional expense would be entailed on the country.—Mr. Brodrick replied: Yes, sir, a number of civilian practitioners are in charge of troops in the United Kingdom and always have been. Ninety-four medical officers retired on pension are employed and more would be employed if they were willing to accept appointments. There would be no objection to the employment of an officer retired upon a gratuity if he were considered suitable for such employment.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ALLAN, E. B., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Officer of Health for Daylesford, Victoria, Australia, vice T. R. H. Willis, resigned.

ARMSTRONG, W. G., M.B., Ch.M. Syd., D.P.H. Camb., has been appointed Medical Officer of Health for the combined Metropolitan Districts, Sydney, New South Wales.

BRONTÉ, A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator for the District of Shannon, New Zealand.

CHAWNER, A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Clay-lane Sanitary District of the Chesterfield Union.

CROOKS, LEWIS A., M.B., C.M., has been appointed Assistant House Surgeon (non-resident) to the Leith Hospital.

ROYAL INSTITUTION.—9 P.M. Mr. H. A. Minchin: Living Crystals.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

HOSPITAL MEDICAL OFFICERS' FEES AT CORONERS' INQUESTS.

IN the Court of Queen's Bench on April 21st an appeal was heard from a decision of the Brentwood county-court judge. The plaintiff was a medical man and the defendant was the coroner for the district. The plaintiff, Mr. C. J. Horner, is the honorary medical officer to a Children's and General Hospital at Walthamstow, and he had attended a child who died in the hospital and on whose body an inquest was held. Mr. Horner made a post-mortem examination and gave evidence at the inquest. For this he claimed a fee of two guineas, which the coroner refused under the well-known section of the Coroners Act which precludes the medical officer o a hospital from the right to receive a fee for such services in the case of an inquest on anyone who has died in a hospital or other public medical institution. A friendly action was brought to test the case and the county-court judge said that the fee was not recoverable. In the appeal it was argued that the hospital in question was not a public institution, but the court dismissed the appeal. There can be no question in this case that Mr. Horner had no right to expect a fee as the law stands. Whether the State has a rigut to expect medical men to give up their time and perform very responsible duties is another question, but the hospital in question is certainly a public institution and Mr. Horner is medical officer of it even though he receives no kind of salary or honorarium.

"UNDESIRABLE PUBLICITY."

To the Editors of THE LANCET.

SIRS,—The attention of the medical staff of the Royal Halifax Infirmary has been drawn to a paragraph under the above heading in THE LANCET of April 23rd. We need scarcely say that the gentleman mentioned neither authorised nor knew of

the insertion of the advertisement and paragraph referred to. The advertisement was drawn up by the senior honorary secretary, but unfortunately was not seen by the medical staff before insertion. The reason why it was not submitted to the medical staff was that the advertisement had to be in on Good Friday and on that day the honorary secretary tried but was unable to communicate with any of the members of the staff, as three were out of town and two were not at home on the afternoon of that day. Anyone reading the advertisement would easily see that it had been drawn up by a layman and that the intention was not to advertise any individual member of the staff but simply to let the public know that the special department had been opened. I am requested by the medical staff to state that neither collectively nor individually have they authorised the form of the announcement and they regret and disapprove of the form in which it appears. I am, Sirs, yours faithfully,

PRIESTLEY LEECH,
Halifax, April 26th, 1898. Secretary to the medical staff.

THE RECENT INQUIRY AT THE BRISTOL CHILDREN'S HOSPITAL.

Two correspondents have written to us asserting that the address affixed to Dr. Christie's letter printed in our columns last week—viz., Church House Children's Hospital, East-street, Bedminster—is a misleading one inasmuch as, they say, there is no hospital at the address. An advertisement from a local paper has also been sent to us in which Church House, East-street, Bedminster, is given as an address where applications may be made concerning a Nursery Aid Society. In this advertisement no mention is made of the House being used as a hospital. If Church House is a *bond-fide* children's hospital we shall be happy to publish Dr. Christie's or anybody else's statement to that effect, but if it is not we strongly advise him to alter the wording of his address for the future.

AN IMPORTANT QUESTION.

To the Editors of THE LANCET.

SIRS,—I should feel glad if you can advise me in the following. For some time I have been attending a patient who suffers from angina pectoris and who has benefited by the treatment. A few days ago a relative called upon me and told me my services would not be required further, as they had called in a chemist who does a lot of doctoring around this neighbourhood to attend him. As I expect the case to end fatally within a short time am I justified in giving a death certificate under the circumstances? Is it legal? and, if so, am I not covering the quack? Thanking you in anticipation,

I am, Sirs, yours faithfully,
April 26th, 1898. M.D.

*** We think that a certificate should on no account be given under such circumstances.—ED. L.

A NEW COPYING MACHINE.

THE Autographic Company of Middlesbrough have brought out a new process for making copies of manuscripts, drawings, plans, and the like. The original MS. or drawing must be executed with a special ink upon a special paper. This paper is covered with some substance which the ink destroys. When the wording or design is complete it is laid face downwards upon the inking sheet. Where the substance on the paper is unaffected by the ink used for writing it comes off on the inked printing sheet, thus forming a protecting film, but the written or drawn lines having destroyed this substance no film is formed by them, therefore the printing ink is exposed. Impressions are then taken off exactly as in the case of an ordinary form of type. The whole apparatus is very simple and inexpensive. It is made in various sizes from ordinary letter size up to brief.

JOHN PAGE HENTSCH APPEAL.

To the Editors of THE LANCET.

SIRS,—I beg to submit a list of subscriptions received up to date.

I am, Sirs, yours faithfully,
410, Brixton-road, S.W., April 26th, 1898. G. DAVID KNIGHT.

HAND-FEED TOOL FOR CHAFF-CUTTING MACHINES.

DEPLORABLE accidents involving the loss of both hands not unfrequently happen to men who have to feed chaff-cutters worked by horse-power or driven by an engine. The usual course of events is that in consequence of something preventing the supply of hay being properly drawn into the machine the man forces it between the rollers with his hand, which is thereupon drawn in along with the hay, and the man, not having the presence of mind to reverse the gear and free his hand, instinctively uses the other hand to help the one which is caught, the consequence being that both share the same fate. To prevent men incurring such great danger by bringing their hands in contact with the rollers Mr. James Gillingham, Prospect House, Chard, Somerset, has devised an instrument which he has called the "Hand Feed." It does not contain any complicated parts, but consists of a plate fixed to a wooden handle and provided with teeth somewhat like those of a rake, curved for the purpose of gathering up the hay. It may be obtained either from the inventor or from dealers in agricultural implements. In illustration of the necessity for some such safeguard Mr. Gillingham has sent us photographs of eight workmen who have lost both hands and either portions or the whole of both forearms by chaff-cutting machinery.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me where I can place a young man suffering from general paralysis of the insane. He is very quiet, orderly, can attend to himself, and does not require much supervision. Terms 12*s.* weekly. I am, Sirs, yours faithfully,
April 27th, 1898. W. B. R.

THE "READORITE."

MR. F. DAVIDSON of 120, Great Portland-street has designed this apparatus for the use of those who have undergone the operation of lens extraction for cataract, engravers, retouchers, and others. It consists of a large bi-cylindrical lens fitted over a writing-desk so that it can be adjusted at any angle or focus. The book or other thing to be seen is, of course, laid on the desk and the lens runs easily along a slide. The lenses are made of different focal lengths. We have tried the apparatus for reading a book printed in "brilliant" type and found it answer well. The price is £3 3*s.*

Medicus.—Many medical men have recently gone to South Africa, but for those who can rough it there is still room. It is our opinion, however, that there is no opening at all for men who are not in the best of health as it is the recent settlements which require to be served, not the old-established towns where the standard of personal comfort is high.

Surgery.—Our correspondent is advised to consult the advice which has been given for several consecutive years in the Students' Number of THE LANCET. Under the circumstances which he mentions we recommend Treves's "System of Surgery," Jacobson's "Operations of Surgery," and Pepper's "Surgical Pathology."

Advice.—Such a circular letter would be in order if it is only sent to the writer's own patients. We understand from our correspondent's letter that he sees the necessity for this limitation.

Mr. James Brown.—We are unable to give the information asked for but have forwarded the inquiry to our local correspondent.

Mr. W. M. Taberner.—We will obtain the information with pleasure.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

EXCERPT FROM

A Study of Some Infant Foods in Comparison with Human Milk.

BY R. H. CHITTENDEN, PH. D.,
Professor of Physiological Chemistry at Yale University.

[Reprinted from *The New York Medical Journal*, July 18th, 1896.]

"That there is no special difficulty in modifying cows' milk so that it will resemble human milk, both qualitatively and quantitatively, is clearly apparent from the analytical results shown in the table:—

	Human Milk.	Milk Modified with Peptogenic Milk Powder.
Specific Gravity	1031	1032
Water	86.73	86.03
Total Solid Matter	13.26	13.97
Inorganic Salts	0.20	0.26
Total Albuminoids	2.00	2.09
Soluble Albuminoids	2.00	2.09
Fat	4.13	4.38
Milk Sugar	6.93	7.26
Reaction	alkaline	alkaline

"Cows' milk, modified by the addition of water, cream, and Peptogenic Milk Powder, offers a product containing to the full extent all of the proximate principles present in human milk and wholly free from extraneous admixtures. The proportion of solid matter, fat, albuminoids, carbo-hydrate, and inorganic salts corresponds as closely as one could ask with what is considered as the average chemical composition of human milk. Further, the process of modification takes into account the radical difference between cows' casein and human casein, and affords a method by which the former can be modified to a closer resemblance to the latter without the addition of any substance that will permanently interfere with the purity of the final product.

"The general resemblance of milk modified by the Peptogenic Milk Powder to the infant's natural supply is a very striking one."

PEPTOGENIC MILK POWDER. Originated and manufactured by FAIRCHILD BROS. AND FOSTER, NEW YORK. Supplied in 1/2 lb. and 1 lb. bottles, at 1s. 9d. and 3s. 4d. each. Specimen and pamphlet upon request to BURROUGHS WELLCOME AND CO., Snow Hill Buildings, London.

TRADE MARK 'ENULE' BRAND

Glycerin Rectal Suppositories.

GLYCERIN 'Enule' Rectal Suppositories are of a new and improved shape, ensuring great ease of insertion and rendering expulsion impossible. They contain 95 per cent. of anhydrous chemically pure glycerin, are free from gelatin, and keep perfectly in tropical climates.

GLYCERIN 'ENULE' RECTAL SUPPOSITORY, WITHOUT SHEATH.

Design Registered.
Nos. 309,366/8.

Top View.

Side View.

GLYCERIN 'ENULE' RECTAL SUPPOSITORY, ENCASED IN SHEATH.

Glycerin 'Enule' Suppositories are guarded from contamination and preserved by a hermetically-sealed sheath of pure tin-foil. This sheath can be instantly stripped off at the moment of using.

Supplied in two strengths.

'ENULE' GLYCERIN (Children's). 'ENULE' GLYCERIN (Adults').

In boxes containing 1 dozen, at 1/- per box.

Burroughs Wellcome and Co.,

Snow Hill Buildings, LONDON.

London Cable and Telegraphic Address:—"BURCOME, LONDON." *Australasian Address:—108, Pitt Street, SYDNEY, N.S.W.*

'Saxin.'

An invaluable sweetening agent when sugar is contra-indicated. It has been aptly described as 'the sweetest thing on earth,' being about 600 times sweeter than sugar, and more delicate in flavour than any other sweetening agent. A small bottle containing 100 or 200 1/4 grs., each equal to one lump of best loaf sugar, can be easily carried in the vest pocket.

Supplied at 7d. and 1s 1d. per bottle.

'Emol-Keleet'

Referring to this product, the *Lancet* says:—"On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in cutaneous diseases, etc., and for allaying irritation. We have not examined a more unctuous earth." 'Emol-Keleet' has proved successful for drying weeping surfaces when all other powders have failed It is also of great service as a diluent for powerful antiseptics.

In boxes, at 9d. each.

RICHEST IN DIASTASE. Maltine RICHEST IN PHOSPHATES AND ALBUMINOIDS.

TIME can prove all things; and time has shown unequivocally the value of the extract of malt known as "MALTINE." Many causes have contributed to this result. We may note that we led the way in perfecting the mode of preparing malt products. By the process which we introduced of concentrating the malt *in vacuo* at a low temperature, by which the whole of the diastase was retained and fermentation prevented, we were able to place before the profession a product for which higher virtues could be claimed than was the case in any other extract of malt.

The general recognition of this fact has enabled us to devote to the production of "MALTINE" a more elaborate plant than has yet been applied to the manufacture of any pharmaceutical product, and accumulated experience has suggested improved processes that are happily illustrated in "MALTINE" to-day. Analysis shows that it contains an exceptional amount of nitrogenous matter and a richness in phosphates and diastase which adds largely to its usefulness as a nutrient as well as to its value as a digestant. The presence of diastase in a high degree cannot be too greatly insisted upon, especially in connexion with the subject of the chemistry of digestion. Physiologists have shown that the presence of certain hydrolytic ferments is essential to the proper preparation of the food for assimilation by the blood-vessels; among these are amylosytic or sugar-forming ferments, which convert starch, glycogen, &c., into sugar with absorption of water—these are present in saliva, pancreatic juice, in the liver and other organs. As it is the case, however, that some cause or causes may interfere with their proper production, as by faulty condition of the blood from which they are secreted, or by some perversion of nutrition in the gland cells by which they are elaborated, it becomes at once apparent that in their absence the necessary changes cannot take place which are essential to the preparation of the food for absorption. Under these circumstances, then, the great value of "MALTINE," as being the means of supplying an artificial ferment of the nature demanded, scarcely requires further demonstration. Dr. FOTHERGILL says: "In order to aid the defective action upon starch by the natural diastase being deficient in quantity or impaired in power, we add the artificial diastase 'MALTINE'." Thus, by means of the administration of "MALTINE," digestion is facilitated, and owing to the high nutritive value of the extract, a tissue-forming and bone-making food is made available for the patient, the good effects of which are not slow in becoming manifest. As a further feature in its favour, we may point out that "MALTINE" is very palatable, and its delicacy of flavour has been highly commended by those who have used it.

Every year that passes shows that medical men and the public insist on pharmaceutical preparations being made palatable; and if composed of drugs which are nauseous or disagreeable, that these two undesirable elements shall be rendered as negative as possible. In preparing "MALTINE" we have paid particular attention to this matter. A good extract of malt should be sweet and pleasant to the palate, so that it not only becomes an agreeable preparation by itself, but also highly useful as a medium for the administration of other drugs the palatability of which falls very far short of that which is acceptable to patients. "MALTINE" will be found to be an excellent medium for administering drugs which have the undesirable characteristic of being distasteful. Its pleasant flavour and convenient semi-liquid consistency are admirably adapted for this purpose; and the measure of its usefulness in this respect is not limited to disguising the taste of a nauseous drug; for, being a food, the patient, so to speak, "kills two birds with one stone"—by combining "MALTINE" with a nauseous dose he both humours his palate besides taking an excellent nutrient. This is a point which should be borne in mind, too, by those who after a dose of medicine are always on the look-out for something with which to "take the taste away." The agreeable taste of "MALTINE," moreover, renders it highly suitable for administration to delicate, badly-nourished children. By many of such, cod-liver oil in any form cannot be tolerated; thus in these cases, where cod-liver oil is indicated, medical men prefer to order "MALTINE," and with results which are very beneficial. "MALTINE" contains so large a quantity of fat-making, heat-producing carbohydrates that for a long time it has been admitted to be an advantageous substitute for cod-liver oil, and its nutritive value is incontestably proved by the patients using it gaining flesh. The excess of diastase in the "MALTINE" enables them to digest more starchy matters than otherwise in their enfeebled state could be possible; and thus "MALTINE" is an almost necessary adjunct in the treatment of al cases of lowered nutrition where digestion of amylaceous material is at a low ebb.

The word "MALTINE" is our Registered Trade Mark.

In prescribing, kindly specify "THE MALTINE MFG. CO."

WE SHALL BE PLEASED TO SEND SPECIMENS FREE OF CHARGE TO MEDICAL MEN.

THE MALTINE MANUFACTURING CO.,

LIMITED,

24 & 25, Hart St., Bloomsbury, London, W.C.

Antiseptic.

For quickly preparing antiseptic solutions of any desired strength. Safer to carry than liquids and more reliable and convenient.

'Soloid' Carbolic Acid, 20 gr.
'Soloid' Mercuric Chloride, 1.75 and 8.75 gr.
'Soloid' Iodic-Hydrarg, 1 and 8.75 gr.
'Soloid' Potassium Permanganate, 5 gr.
'Soloid' L.G.B.

Full list and prices on application.

Anæsthetic.

Enable the material for instantly preparing fresh, active solutions, possessing full anæsthetic power, to be carried in the pocket.

'Soloid' Cocaine Hydrochloride, 1/2, 1 and 5 gr.
'Soloid' Eucaine Hydrochloride, 1 and 5 gr.
'Soloid' Cocaine and Eucaine Hydrochlor., 1/2 gr. each.

Specimens gratis on request.

TRADE MARK **'Soloid'** BRAND

Compressed Products.

The word 'Soloid' is a brand which designates fine products manufactured by

Burroughs Wellcome and Co.,

Snow Hill Buildings, LONDON, E.C.

108, Pitt Street, SYDNEY, N.S.W.

Gynecopathic.

Replace bulky and cumbersome bottles of antiseptic and astringent solutions. More pleasing to the patient, and being portable, secure regularity of treatment.

'Soloid' Alum Compound.
℞ Alum., gr. 15. Zinci Sulph., gr. 15.
'Soloid' Sodium Biborate Comp.
℞ Sodii Bibor., gr. 20. Tinct. Opii, min. 10.
'Soloid' Zinc & Tannin Compound.
℞ Zinci Sulph., gr. 5. Acid. Tannic., gr. 1. Ext. Opii, gr. 2. Plumbi Acetat., gr. 10.

Specimens and particulars gratis.

Nasal.

For conveniently preparing nasal douches, sprays, etc. This class includes various combinations of alkaline and antiseptic agents with or without volatile oils.

'Soloid' Nasal (Alkaline).
'Soloid' Nasal (Antiseptic and Alkaline).
'Soloid' Nasal (Compound Eucalyptia).
'Soloid' Nasal (Compound Phenol).
'Soloid' Naso-Pharyngeal.

See Wellcome's Medical Diary, p. 75.

[COPYRIGHT.] H 44

'KEPLER' MALT EXTRACT

HAS always retained its superiority because it is the uniform product of the finest winter-malted barley. No inferior cereals are used, and the special 'Kepler' process ensures a full percentage of diastase. As a food and as a digester of foods it is unrivalled. "Its qualities are not deteriorated nor its flavour spoiled."

Ready this day, 400 Illustrations, price 21s. net.

A Manual of Surgery.

By WM. ROSE, M.B., B.S.Lond., F.R.C.S., Professor of Surgery in King's College, London; Consulting Surgeon to the Royal Free Hospital; and ALBERT CARLESS, M.B.Lond., F.R.C.S., Teacher of Operative Surgery, King's College; Senior Assistant Surgeon, King's College Hospital.

Ready Next Week.

Outlines of Practical Surgery.

SPECIALLY DESIGNED FOR STUDENTS.

By WALTER G. SPENCER, M.B., M.S. Lond., F.R.C.S., Surgeon to the Westminster Hospital; Examiner to the Conjoint Board, Royal Colleges of Physicians and Surgeons.

575 Coloured Illustrations, with Descriptive Text. Translated and Edited by R. A. YOUNG, M.D., B.Sc. Lond.

Bound half morocco, gilt edges. Price £1 11s. 6d. net.

Brass's Atlas of Histology.

The most beautiful and artistic medical work ever produced.
A magnificent gift or prize book.

This day, with numerous Tables, price 10s. 6d.

Practical Toxicology for Practitioners and Students.

By Professor RUDOLF KOBERT. Authorised translation from the German by L. H. FRIEDBURG, M.D.

A complete Text-book of General Toxicology, Special Toxicology, Metabolism, &c.

With numerous Coloured Plates, Statistical Tables, &c., price 12s. 6d.

Theory & Practice of Vaccination.

By ROBERT CORY, M.D. Cantab., F.R.C.P. Lond., Physician in Charge of the Vaccination Department, St. Thomas's Hospital; Teacher of Vaccination in the University of Cambridge.

"Dr. Cory's experience is almost unique, and the pages of his book abound with points of deep interest."—BRIT. MED. JOURNAL.

Second Edition, price 7s. 6d. net.

Massage:

ITS PHYSIOLOGICAL EFFECTS AND THERAPEUTIC USES.

By A. SYMONS ECCLES, M.B., M.R.C.S. Eng.

"Dr. Eccles has very happily succeeded in producing a scientific though an essentially practical treatise on the subject."—MEDICO-CHIR. JOURNAL.

Price 10s. 6d., profusely Illustrated.

Manual of Mental Diseases.

By A. CAMPBELL CLARK, M.D., F.F.P.S.G., Mackintosh Lecturer on Psychological Medicine, St. Mungo's College, Glasgow; Medical Superintendent of Lanark County Asylum, Hartwood.

"The various recognised forms of insanity are lucidly discussed in detail. ..... The part dealing with causation, prognosis, and treatment is distinctly good. Most important are his remarks on the insanities of pregnancy and lactation, and also on puerperal insanity. The practical value of these chapters is very considerable."—THE LANCET.

Now ready, price 10s. 6d.

Death and Sudden Death.

A MEDICO-LEGAL HANDBOOK.

By Professor BROUARDEL, of Paris. Authorised Translation by F. LUCAS BENHAM, M.D. Lond., M.R.C.P.

"We have nothing but a hearty welcome to accord to this work."—BRITISH MED. JOURNAL.

"The book is brimming with information and points of practical interest."—MEDICAL PRESS.

Second Edition, ready Next Week, Coloured Plates.

Applied Bacteriology:

A MANUAL FOR STUDENTS AND PRACTITIONERS.

Containing the latest Methods of Research and their application.

By T. H. PEARMAIN and C. G. MOOR, M.A. Cantab., F.C.S. With 81 Illustrations in Colours.

With over 300 Engravings and Coloured Plates, price 15s.

Manual of Physiology.

By Professor G. NEIL STEWART, M.A. Cantab., M.D., D.Sc.

"It is one of the very best English text-books."—THE LANCET.

"We do not know of one that comes up to the ideal text-book as does Professor Stewart's volume."—BRITISH MED. JOUR.

This day, price 4s., Illustrated.

The Diagnosis of Disease.

By J. PORTER PARKINSON, M.D., M.R.C.P. Lond., F.R.C.S.Eng., Medical Registrar to the Westminster Hospital; Assistant Physician to the Hackney Children's Hospital.

Specially written for the use of Students Preparing for Examination, and for Junior Practitioners.

This day, price 7s. 6d.

Respiratory Exercises in the Treatment of Disease.

NOTABLY OF THE HEART, LUNGS, NERVOUS AND DIGESTIVE SYSTEMS.

By HARRY CAMPBELL, M.D., B.S. Lond., F.R.C.P. Lond., Physician to the North-West London Hospital, and to the Hospital for Nervous Diseases.

Price 6s. net, with numerous Photographic Plates.

Röntgen Rays in Medical Work.

A SYSTEMATIC GUIDE TO THE USE OF THE X-RAYS IN MEDICINE AND SURGERY.

By DAVID WALSH, M.D. Ed., Hon. Sec. London Röntgen Society.

With Section dealing with Electrical Methods and Apparatus by J. S. GREENHILL.

"The x-ray pictures are the best we have seen."—THE LANCET.

Price 5s.

Cancer Operations, their Objects and Limits.

By Prof. WATSON CHEYNE, F.R.C.S., F.R.S., Surgeon to King's College Hospital.

"Every practical surgeon should consider it a duty, as well as a privilege, to carefully examine these lectures."—MEDICAL PRESS.

Second Edition, price 5s.

The Modern Treatment of Stone in the Bladder.

By P. J. FREYER, M.A., M.D., M.Ch., Surgeon to St. Peter's Hospital for Urinary Diseases; late of H.M. Indian Medical Service.

"Most practical, admirable in style and method."—MEDICAL PRESS.

"A concise, clearly written, and reliable guide."—BRIT. MED. JOUR.

Chemical Notes and Equations

(INORGANIC AND ORGANIC) FOR STUDENTS.

By G. H. GEMMELL, F.I.C., F.C.S. Price 5s.

Vest-Pocket Medical Dictionary,

INCLUDING PRONUNCIATION.

By ALBERT H. BUCK, M.D. 529 pp., bound roan. Price 3s. net.

London: BAILLIÈRE, TINDALL, & COX, 20 and 21, King William Street, Strand.

**** ***Full Catalogue (English or French) Post Free on application.***

The Milroy Lectures

ON

THE NATURAL HISTORY OF VACCINIA.

Delivered before the Royal College of Physicians of London

BY S. MONCKTON COPEMAN, M.A., M.D. CANTAB., M.R.C.P. LOND.,

MEDICAL INSPECTOR TO HER MAJESTY'S LOCAL GOVERNMENT BOARD; LECTURER ON PUBLIC HEALTH IN THE MEDICAL SCHOOL OF WESTMINSTER HOSPITAL.

LECTURE I.[1]

Delivered on May 3rd, 1898.

MR. PRESIDENT, CENSORS, AND GENTLEMEN,—I feel that it would be superfluous for me to dwell at any length upon the very great gratification it affords me to have been selected to deliver the Milroy Lectures. I can only assure you of my appreciation of the honour you have been pleased to confer upon me and express my pleasure at being granted the opportunity of addressing you on certain points in connexion with the Natural History of Vaccinia—a subject, as it seems to me, specially appropriate to the present occasion, seeing that this year not only marks the centenary of Jenner's first publication but also the inauguration of a new era in the practice of vaccination in this country.

Just one hundred years ago, in the summer of the year 1798, there burst upon the world a treatise the publication of which marked a never-to-be-forgotten event in the history of scientific medicine. This truly epoch-making publication was entitled "An Inquiry into the Causes and Effects of the Variolæ Vaccinæ, a disease discovered in some of the Western counties of England, particularly Gloucestershire, and known by the name of the cow-pox." It was the work of Edward Jenner, a country medical practitioner living at Berkeley in the vale of Gloucester. But in order adequately to appreciate the far-reaching importance of his work, first submitted to the world in the comparatively small compass of a quarto pamphlet of seventy-five pages, it is necessary for us to endeavour to transport ourselves in thought backwards for a century or more in order to realise approximately the truly terrible and far-reaching nature of the scourge the only efficient preventive of which was first introduced to the human race through the publication of Jenner's "Inquiry."

Thus Macaulay, in an oft-quoted passage in which he refers to the death in 1694 of Queen Mary, wife of William III., writes: "That disease over which science has since achieved a succession of glorious and beneficent victories was then the most terrible of all the ministers of death. The havoc of the plague had been far more rapid, but the plague had visited our shores only once or twice within living memory and the small-pox was always present, filling the churchyards with corpses, tormenting with constant fears all whom it had not yet stricken, leaving on those whose lives it spared the hideous traces of its power, turning the babe into a changeling at which the mother shuddered and making the eyes and cheeks of the betrothed maiden objects of horror to her lover."

The ever-present danger and the lively apprehensions engendered through recognition of the slight chance of anyone evading the onslaught of the scourge between childhood and maturity is also brought out somewhat forcibly in an extract from the "Pages from a Private Diary" in the January number of the *Cornhill Magazine* for the present year. It runs as follows: "I came on a curious passage in a letter of Mrs. Waller's to her banished son about the marriage of his daughter. She wishes to know what dowry he is prepared to give. 'I am not in haste to marry her, she is young enough to stay, but the danger is if she should catch the small-pox or her beauty should change it would be a great loss to her.' Everybody," adds the writer, "is familiar with the frequent references to small-pox in the letters and memoirs of the seventeenth century. Pepys is full of it; but I have never met with a passage that brings so keenly home to me the nearness of the risk."

In this connexion, also, may be mentioned a record of an epidemic of small-pox in the small town of Ware in 1722. The population at the commencement of the epidemic was 2515, of whom 1601 are stated to have had small-pox previously, the remaining 914 being therefore presumably susceptible to the disease. During the course of the epidemic, of these 914 persons 612 were attacked, of whom 72 died. The remaining 302 persons who escaped attack are spoken of in the record in quaintly dogmatic fashion as "to have the small-pox." We possess also a record of an epidemic which occurred at Warrington in 1773, where out of 473 deaths from all causes during the year among a population estimated at 8000 no less than 211 were attributed to small-pox. And from a report by Haygarth of Chester we learn, as in the case of Ware, how small a proportion of the population in these places had not suffered from small-pox at one time or another. The actual number of persons attacked at Chester in 1774 was 1202, of whom 202 died, the total population of the town being at this time 14,713. But as the result of an investigation carried out at the commencement of the following year it becomes fairly certain that previously to the outbreak in 1774 there were in Chester, of the whole population, only 2262, or 15 per cent., who had not already had the disease. Consequently, of the remaining susceptible portion of the inhabitants more than half were attacked before the end of the year. These epidemics at Chester and Warrington also illustrate a marked characteristic of small-pox in the eighteenth century which is also noticeable in the records of this and probably also of preceding periods in which the age of those attacked is given—namely, the large proportion of the deaths contributed by children under ten years old. In the Warrington outbreak of 1773 and also in that which appeared in Chester in the following year not a single death occurred in persons above this age, while of the 202 deaths at Chester no less than a quarter of the total number were accounted for by infants of less than twelve months. Other instances of a like condition of affairs noted in the recent Royal Commission's final report refer to Kilmarnock, where out of 622 deaths occurring between 1728 and 1763 of which with nine exceptions the ages are recorded, only seven were of those above ten years, and to records obtained from the burial registers of the graveyard of St. Cuthbert's, Canongate and Buccleuch-street, Edinburgh, from which we learn that during the years 1764–83, of every thousand deaths from small-pox at all ages no less than 993 of these deaths were among children below ten years of age.

In considering the question of ratio of deaths from small-pox to the living population we are beset with several difficulties. In the first place, as Dr. J. C. McVail points out, in no single epidemic in London in former centuries was it possible to see small-pox at its worst, since epidemics followed one another at such rapid intervals that of necessity the material on which at any one period their energy could exert itself was extremely limited. "At any given date the great bulk of the people had already had small-pox, and it was only among a fraction that there was room for the disease to spread. Yet it was among such fractions of the population that small-pox every few years slew its thousands in London alone." If we desire to obtain an illustration of the full effects of an invasion of small-pox when not thus hampered by the existence of very general immunity the result of former epidemics we must turn our attention to some particular locality which owing to its isolated position has previously escaped invasion. In illustration of this point we may take the case of Iceland, where during 1707–9 out of a total population of 50,000 no less than 18,000 persons died from this disease.

Aitken calls attention to the fact that since the date of the first accounts by the Arabian physicians of the ravages of small-pox in Mecca the history of this disease may be arranged in three great stages, each of which is characterised by remarkable epochs. The first of these periods is marked by an improvement in the treatment of small-pox, the merit of this revolution in medical practice being due to Sydenham. In few diseases, indeed, has medical opinion undergone in the course of years a more obviously beneficial change. The second stage is marked by the discovery of the singular phenomenon that the virulence of the poison of small-pox is greatly mitigated by introducing or engrafting the disease into the system through the cutaneous tissues,

[1] Lecture II. was delivered on May 5th and Lecture III. will be delivered on May 10th.

thereby causing the transference of the disease from one person to another by inoculation. To Lady Mary Wortley Montagu, in 1722, we owe the introduction of the practice of inoculation into this country, a deed which must be considered as one of no little bravery when measured by the knowledge possessed by physicians in those days. The third great era is characterised by the remarkable discovery which has rendered the name of Jenner immortal—namely, the modifying and protecting influence of vaccination.

With the therapeutic treatment of small-pox we are not on the present occasion concerned. On the other hand, the practice of inoculation, although prohibited by law since the passing of the first Vaccination Act, is yet deserving of some attention. We shall then be in a position more fitly to discuss the question of the discovery of vaccination and of the evidence on which its employment was originally based. There will remain for our consideration a review of such accretions to our knowledge of the subject of vaccination, more particularly from the standpoint of pathology, as the progress of scientific research during the century since Jenner wrote has rendered available. To marshal these in order, to try to indicate their relative importance, and to direct attention to their bearing on the necessity for certain changes in the regulation and practice of vaccination, as these obtain at the present time, is the chief aim which I have had in view in the preparation of these lectures.

INOCULATION.

Recognition in former times of the certainty that almost everyone would suffer attack by small-pox during some period of his or her life and the lively horror inspired by the disease by reason not only of the high fatality inseparable from it but also of the maiming and disfiguring effects on a large proportion of those who survived its invasion naturally turned men's minds the world over to the question as to whether it were not possible to devise some method for mitigating the virulence of the plague. Whence, however, was originally derived or by whom accidentally or otherwise was discovered the artificial method of communicating small-pox which came to be known by the term "inoculation" it is at the present day impossible to say. According to tradition the process of inoculation has been in use among the Brahmins in India for centuries and a similar claim has been made on behalf of the Chinese. There can be little doubt that in China a method of artificially communicating small-pox was in vogue long ages apparently before the disease had obtained recognition in Europe, but the process was essentially different from inoculation properly so-called, consisting as it did of inserting small-pox crusts into the nostril of the patient, whereby the disease was communicated by way of the respiratory tract. Coming to comparatively recent times, however, we have definite evidence that inoculation was practised in Turkey early in the eighteenth century.

In the 29th volume of the Philosophical Transactions of the Royal Society may be found references to the process as observed in 1713 by Dr. Emanuel Timoni of Athens and in 1716 by M. Pylarini, then Venetian Consul at Smyrna. But it would seem that their description made little, if any, impression at the time and, although published in the records of the Royal Society, passed almost at once into oblivion. The actual introduction of inoculation into England was brought about through the instrumentality of Lady Mary Wortley Montagu, who, apart from her social status as the wife of the English Ambassador at the Ottoman Court, has achieved for herself lasting recognition in literature by reason of her attainments in the gentle art of letter-writing. Indeed, Professor Rayleigh in a recent lecture at the Royal Institution gave it as his opinion that in this respect she should be placed second only to Madame Sevigné. Writing from Adrianople in 1718 she says: "The small-pox, so fatal and so general amongst us, is here entirely harmless by the invention of *engrafting*, which is the term they give it. Every year thousands undergo the operation; and the French Ambassador says, pleasantly, that they take the small-pox here by way of diversion, as they take the waters in other countries. There is no example of anyone who has died in it; and you may believe I am well satisfied of the safety of this experiment, since I intend to try it on my dear little son. I am patriot enough to take pains to bring this useful invention into fashion in England." Lady Montagu had indeed the courage of her opinion, and the first person inoculated in England was her daughter. This first operation by Dr. Maitland in April, 1721, was shortly followed by the inoculation of a child of her family physician, Dr. Keith. Next an experiment on a larger scale was carried out on certain condemned felons who were offered the alternative of submitting to the operation. No ill result having been witnessed thus far, King George I., who had been much interested in the matter, was himself inoculated, as also were several members of his family. Apparently, however, the method did not generally commend itself to public taste; moreover, it was discovered that, contrary to anticipation, persons inoculated with small-pox became themselves centres of infection and, perhaps for the reason that no serious attempt was made at that time to diffuse information on the subject, it was not until thirty years or more subsequently to its introduction into this country that inoculation as a prophylactic against small-pox became practised to any considerable extent.

In his "Synopsis Medicinæ," published in 1761, Dr. John Allen, a Fellow of the Royal Society, gives the following curious directions for the inoculation of the small-pox: "First, a little quantity of purulent Matter must be procured, about 5 or 6 drops taken from the Pustles of some young Person, who has the benign Small-pox of the distinct Kind, which must be brought to the Place where the Operation is to be performed in a Small Vial or in a little Pill-Box; and when all Things are prepared, the Surgeon is to make two small Wounds, one on the Arm, and the other on the Leg, of the Opposite Side; and the aforesaid variolous Matter is to be applied to the Wounds on Dossils of Lint, and a Bandage to be made over it. There is no occasion to make the incisions deeper than just through the Skin, nor any longer than a Barley-Corn. After 24 hours the Dossils may be removed, and the Ulcers dressed with Diachylum Plaister or Cole-Wort leaves once or twice a day, according as more or less Matter is discharged. This being done, the Distemper will gradually be produced; and it is usual for the following Symptoms to arise. About the eighth day after the Operation some Pustles begin to appear not unlike to those that are commonly seen in the distinct Kinds, a little Fever having preceded the Eruption and the other usual Symptoms, but more mild and gentle. As to the places where the Incisions are made, the 4th Day they grow red and are inflamed, on the 6th they tend to Suppuration and discharge an ichorous Pus. Indeed, about the time of the Eruption of the Pustles whilst the little Fever lasts the Ulcers discharge somewhat less; but after the Eruption, even until the Decline of the Pustles, the Pus increases daily and after that it again gradually diminishes, so that commonly in five weeks time the Ulcers are quite dried up. By how much the greater the discharge of purulent Matter is by these artificial Ulcers so much the milder will the Distemper be. In the general it is observable that the Small-pox procured by Inoculation are of the distinct Kind, for the most part void of Danger, that the Pustles are few in number, and pit very little. Very often, however, there follow after them Tubercles and Abscesses, some indeed but slight ones but sometimes very malignant ones, and exceedingly difficult of Cure. To prepare the Body for Inoculation a great many talk much of Bleeding, of giving Emeticks and Cathartick. But in truth, if the Person to be Inoculated has Youth on his side, is of a good habit of Body, and in Perfect Health, none of these things seem to be necessary. It is requisite only, that he take care to observe a temperate Regimen for some time before the Operation. When the Operation is performed the Person need not be kept under any strict Confinement, but may live pretty much after his accustomed Manner, excepting that it will be prudent to forbid him the eating any Flesh-Meat. When the Small-Pox are come out the same Regimen is to be observed as is usual in the distinct Kind, got in the common way; and if there be occasion for anything at all of Medicine, these procured by Art require the same Method of Treatment, as the benign discrete Small-Pox in the natural way."

The subsequent extensive diffusion of the practice of inoculation in this country was undoubtedly due in large measure to the labours of two brothers named Sutton and also of Adams and of Dimsdale, of whom the last named had a barony conferred upon him in commemoration of his having successfully inoculated the Empress Catharine of Russia. The Suttons—two brothers, Robert and Daniel, who lived at Bury St. Edmunds, Suffolk, and Ingatestone in Essex respectively—although not medical men, introduced, or rather revived, the greatly improved method of treating the patients under their

charge. They were extraordinarily successful in the results which they obtained and, indeed, claim to have inoculated no less than 20 000 persons without losing one as the direct result of the operation. Acting on the instructions originally laid down by Sydenham for the treatment of ordinary small-pox—the form of treatment to which, by the way, his contemporaries obstinately refused their adherence—the Suttons adopted and caused their patients strictly to observe what was known as "the cooling treatment," a method much akin to that which appears to have been pursued with good results by the Turkish operators from whom Lady Montagu first derived the knowledge of the process of "engrafting." In the hands of Daniel Sutton, who became specially famous for his successful inoculations, "the great secret of his success seems to have consisted in his making one puncture only; exposing his patients much and often to a cool atmosphere; supplying them freely with refrigerant drinks; and restricting them to a spare diet." By attention to the mode of life and general treatment of persons undergoing the process, together with careful selection of the sources (preferably the primary vesicle) from which the virus was obtained, Adams indeed succeeded in gradually evolving a strain of virus of such tenuity as to produce in a considerable majority of instances nothing beyond a single vesicle at the original site of puncture. The general eruption typical of the disease as contracted in the ordinary manner was in these cases either entirely absent or represented by at most a very few secondary vesicles only. Although doubtless the extremely mild form of the disease thus artificially produced was none the less contagious, the visible effect produced so closely resembled the results then beginning to be known as following on the Jennerian process of vaccination that numbers of Adams's patients could hardly be persuaded that he had not, contrary to their desire, intentionally vaccinated rather than variolated them.

There has always been considerable controversy as to the efficacy of the process of inoculation in restraining the ravages of small-pox, the matter being rendered the more difficult since it is almost impossible to arrive with any accuracy at what may be thought of as the average death-rate of the natural disease which in pre-inoculation times is known to have varied greatly in different epidemics. If, as has been frequently asserted, the average mortality in natural small-pox may be taken as being one in five or six, and, on the supposition that in the majority of cases at any rate inoculation prevented subsequent invasion by small-pox, then it is quite evident that the process was of the utmost value to the persons inoculated.

The statement of the Suttons, already mentioned, that inoculation in their hands was unattended with fatal results is perhaps exaggerated, as may also be the declaration of Baron Dimsdale that in a series of 1500 cases no death had occurred. Nevertheless the records of the Small-pox Hospital for a series of years show that we shall not greatly err and shall indeed be probably within the mark if we accept Dr. Gregory's estimate of 1 death in 500 inoculations as approximately correct. There is, however, perhaps ground for suspicion that inoculations performed in the face of epidemic small-pox were more prone to be fatal than were inoculations undertaken when the disease was not prevalent. On the other hand, we must bear in mind that the general diffusion of inoculation brought under the influence of the disease, although possibly in a mild form, large numbers of persons who otherwise might probably have escaped infection.

It is, I think, hardly possible better to sum up the matter than in the words of Sir Thomas Watson: "The advantages of the practice of inoculation to the individual, supposing him doomed to have small-pox, were great and obvious; to the community at large they were very doubtful. It gave the undoomed individual for certain an ugly disease which was comparatively free from danger in exchange for the chances, on the one hand of contracting a very hazardous form, and on the other of escaping altogether from any form, of variola. We need not inquire which is the most eligible branch of this alternative; we know which was by most men actually chosen. But the practice of inoculation, by carrying the virus and the disease into every village throughout the length and breadth of the land, filled the country with contagion, ensured the disease to all who were subjected to the operation, and diminished to all who were not the chances of escaping it. No doubt the distemper was produced artificially in many more persons than would have caught it naturally had inoculation never been thought of, so that while the relative mortality—the percentage of death from small-pox—was lessened by this practice the absolute mortality was fearfully increased. Such at least is the judgment expressed by most who had thought and written on the subject."

VACCINATION.

It was during Jenner's apprenticeship to Mr. Ludlow, a medical man practising at Sodbury, near Bristol, that his attention first became directed to a belief, widely prevalent in Gloucestershire during the latter half of the eighteenth century, that those persons who in the course of their employment on dairy farms happened to contract cow-pox were thereby protected from a subsequent attack of small-pox. Although himself a native of Gloucestershire he does not appear to have been aware of the local tradition previously to joining Mr. Ludlow at Sodbury. It was while working here that his interest became aroused by a casual remark made by a young countrywoman who happened to come one day for advice and who, on hearing mention made of small-pox, immediately volunteered the statement that she could not take that disease as she had had cow-pox. On coming up to London in 1770 to finish his medical education Jenner entered at St. George's Hospital and became also a pupil of John Hunter, with whom he speedily became a great favourite. With Hunter he discussed the question of the protective power of cow-pox over small-pox, but the great anatomist does not appear to have attached much importance to the matter although subsequently on several occasions he referred to it both publicly and in private. In 1773 Jenner returned to his native village of Berkeley, where he commenced to practise as a medical man. The impression which had been made on him in his student days as to the possibility of obtaining protection against small-pox still persisted, becoming, indeed, stronger as time went on. It would appear, indeed, to have been ever present in his mind and at length he determined to put the matter to the test of direct experiment. It was not, however, until May 14th, 1796, which has been appropriately termed the birthday of vaccination, that he commenced actual experiments. On this day he vaccinated James Phipps, a healthy boy about eight years old, by inserting into two superficial incisions on his arms matter taken from a vesicle on the hand of Sarah Nelmes, a dairymaid, who had been infected while milking her master's cows. The result of this experiment, the details of which are so well known as to need no mention here, must have afforded Jenner the most lively satisfaction, confirming as it did what up to that time had been a pious opinion only. "But the most agitating part of the trial still remained to be performed. It was needful to ascertain whether he (Phipps) was secure from the contagion of small-pox. This point, so full of anxiety to Dr. Jenner, was fairly put to issue on the first of the following July." Variolous matter taken directly from a pustule was carefully inserted by several incisions, but no disease followed. Having succeeded in communicating cow-pox from one human being to another by implantation of the virus in the skin, the next step was obviously to attempt its transference to yet another subject and so on, if possible, through an indefinite series, in order to ascertain whether its protective power was thereby diminished. Through lack apparently of material Jenner's work was interrupted until the spring of 1798 when a simultaneous outbreak of cow-pox and "grease" afforded him the further opportunity he desired. A few months later he published his "Inquiry" in which were set out the results of his observations. The appearance of this work was the signal for an extraordinary wave of enthusiasm which spread so rapidly that within a few years only of Jenner's announcement a knowledge of his method of preventing small-pox had extended to almost every portion of the civilised world.

The experience of the past century, culminating in the definite pronouncement in 1896 of the Royal Commission on Vaccination, having fully justified the principle of Jenner as to the prophylactic power of vaccination, it may be of interest to determine what light pathology is capable of throwing on the relationship which may be thought of as existing between variola and vaccinia.

THE RELATIONSHIP OF VARIOLA AND VACCINIA.

Although it is clear from Jenner's writings that he believed vaccinia to be nothing more or less than "small-pox of the cow" his theory appears not to have received general support even in his own day, and from that time onwards the value of the practice of vaccination has by some been

impugned on the plea that inoculation of one disease, "cow-pox," could not be expected to exert any really protective influence against the ravages of small-pox, a disease supposed by them to be of totally different origin. And if the thesis of essential difference between these maladies were capable of demonstration no doubt the objection would be of considerable weight; for there exists but little well-authenticated evidence that the living virus of one disease is capable when inoculated into an animal of affording protection against the effects of inoculation of the virus of another and totally different disease, although no doubt when two different viruses are inoculated at nearly one and the same time the incubation period of one or other of them may be modified as to duration.

In his first paper Jenner, as has been said, advanced the thesis that small-pox and cow-pox are identical; but even at the present day controversy wages hotly around this question and it still awaits a definite solution. There can, however, be no objection to our speaking of vaccinia as "one with small-pox," since it matters little from our present point of view whether small-pox on its transference from man to the bovine animal becomes actually transformed or, as some would maintain, merely modified. During the long period which has now elapsed since the introduction of vaccination many observers have set themselves the task of attempting by experimental methods to solve the problem of the true relationship of variola to vaccinia. These attempts have all been directed to the possibility of giving rise to cow-pox by the introduction in one or another manner of the virus of small-pox into the system of the bovine animal. In the great majority of such attempts, which are vastly more numerous than is generally supposed, the results have been entirely negative, although so numerous have been the experimenters who from time to time have attacked the problem that the total number of instances in which an apparently successful result has been obtained is now considerable. As far as I am aware the first recorded experiments are those of Gassner of Gunzburg in 1801, who succeeded after no less than ten fruitless attempts in directly inoculating a cow with small-pox virus. The lymph thus obtained was employed for the vaccination of four children, from whom seventeen others were subsequently vaccinated. None of these exhibited any signs of small-pox. Viborg of Copenhagen, in 1807, is stated to have also been successful in variolating the cow. Basil Theile of Kasan twice (in 1836 and 1837 respectively) succeeded in inoculating the cow with small-pox matter and in vaccinating children with the lymph thus obtained. In the light of recent work on this subject his conclusions are of much interest. As stated by himself they are: (1) the so-called vaccine disease is not an eruptive disease peculiar to the cow, but it is produced in it by the transmission of human small-pox to it, and the man and not the cow, as has hitherto been thought, is the source of the disease; (2) the mild disease thus caused in the cow can by direct transmission from the cow to man produce in him as mild a disease, which gives protection against the natural small-pox. Theile also described a method by which he claimed to have brought about such modification of small-pox virus as to render benign its action on the human subject without the intermediate stage of implantation on the tissues of the cow. This altered potency of the material was brought about, according to his statement, by first keeping the small-pox lymph for a period of ten days between two slips of glass, after which milk was added to it and the resulting mixture employed for the vaccination of children. The same process was carried through with the lymph obtained from the first and following series of children vaccinated, until after ten generations addition of milk was found to be no longer necessary.

Seeing that at this date (1836–38) true cow-pox was so much more widespread than at present, that at the commencement of the century Jenner confidently looked forward to its occurrence every year, and that in consequence the majority of milch cows were liable to become infected at one or another period of their existence, this empirical method of Theile bears a curious and noteworthy resemblance to one of the methods proposed by Koch for the treatment of rinderpest. This consists in the injection into susceptible animals of a mixture composed of a small proportion of virulent blood diluted with a much larger quantity of serum obtained from an immune animal. Milk, of course, is merely an emulsion due to suspension of fatty particles in a fluid which may be regarded as blood serum, so that it is conceivable that milk obtained from a cow which had suffered not long before from cow-pox and had so become, for the time at any rate, immune, might so far modify small-pox lymph added to it as to produce some such effect as noted by Theile when the mixture was used for purposes of inoculation. I have been unable to find any records dealing with a repetition of these experiments, but it would be interesting to make investigation into the possibility of producing a similar lessening in virulence of small-pox lymph by admixture with the blood serum of a calf which had been vaccinated some few weeks beforehand.

Ceely, in February, 1839, inoculated three sturks with variolous lymph, with the result that in two of the three he eventually obtained in due course what he considered to be vaccine vesicles. From these, lymph stocks were established which at one time came into such extensive use that in the course of a few months at least a couple of thousand children had been vaccinated therefrom. In his paper recording these experiments he states that on former occasions, even though working purposely at different times of the year, he had altogether failed in attempts to variolate the cow. In order to test the measure of protection afforded to these children by his variola-descended lymph Ceely tried on a number of them the effect of subsequent inoculation at varying intervals of time from their vaccination. In no case did he obtain any greater result locally than on the authority of Willan is known to have attended the test inoculations employed by Jenner and Woodville.

Unfortunately, owing to the particular methods used by Ceely in his variolous inoculations of cows some doubt is thrown on the value of the results obtained by him. He was, according to his own account, working simultaneously with both variolous and vaccine lymph, so that it is difficult to exclude the possibility that his instruments may have unintentionally served to convey the infection of both diseases at one and the same time.

Several years before the commencement of his inoculation experiments Ceely had made trial of a method originally employed by Sonderland of Barmen (1830), who claimed to have infected cows with the contagion of variola by way presumably, of the respiratory tract. This he did by enveloping them in blankets taken from the bed in which a patient had died from small-pox and by hanging other blankets similarly infected around the head of each cow in order that the animal might breathe in the "effluvium" arising therefrom. It is stated that these cows subsequently manifested symptoms of cow-pox and that from this source lymph was obtained and used on the human subject with the result that typical vaccine vesicles were produced. Ceely failed, however, in his attempt to bring about infection in similar fashion, as, indeed, have numerous observers in various parts of the world. Yet Ceely has himself recorded an occurrence observed by him in 1840 which, although apparently but little known, is of interest in this connexion. He relates an instance in which five out of eight milch cows sickened with cow-pox within twelve or fourteen days of their having been seen to be licking over a quantity of flock from the mattress on which a patient had died from confluent small-pox and which had been spread out in a field for purification. Careful inquiry at the time appears to have left no doubt that the animals, which had been on the same farm for a considerable period, were in good health at the time of their admission to the meadow in which the bedding was exposed and also that there had not been any other case of cow-pox in the neighbourhood. The fact that all the animals became affected simultaneously and after a period corresponding to the usual incubation period of variola certainly affords some reason for the assumption that the outbreak owed its origin to the animals being exposed to the "effluvium" from the infected bedding. It is, of course, possible that infection by way of the digestive tract may have been a factor also in this case, since Chauveau and other observers have shown experimentally that such result may be possible, a number of cases having now been recorded in which vaccinia has been communicated both to the human subject and also to the lower animals by the ingestion of vaccine lymph or powdered vaccine crusts.

There surely has seldom been so indefatigable a repeater of experiments as Badcock, the Brighton chemist, who during a period of about twenty-five years performed more than five hundred variolous inoculations. In December, 1840, Badcock, who had commenced his work without knowledge of Ceely's slightly earlier work, first succeeded in variolating a cow from which he carried on a stock of what was indistinguishable from genuine vaccine lymph. Although he

subsequently met with similar success on no less than thirty-seven separate occasions, the difficulty and uncertainty of the work will be appreciated on consideration of the fact that those experiments which eventuated in success represent but 7 per cent. of the total number. The lymph obtained by Badcock as the result of his variolation experiments has been largely employed; he supplied it to hundreds of medical practitioners and many thousands of children are said to have been successfully vaccinated with it. About twelve years (1852) after Badcock had obtained his first successful result two American physicians, Adams and Putnam, were equally fortunate and were able in consequence, as reported at the time in a Boston daily paper, to furnish all the vaccine matter requisite for use in the city and neighbourhood.

In 1865 a commission appointed by the Society of Medical Sciences at Lyons, having Chauveau as its head, reported the results of a comprehensive series of experiments carried out by it during the two preceding years, the results of which were completely at variance with those obtained by previous investigators. These results have been admirably summarised in the Report of the English Royal Commission on Vaccination. "Inoculation of the cow or heifer with small-pox matter in any one of the thirty animals used did not give rise to a vaccine vesicle; nevertheless a definite result was obtained, in the form, however, not of a vesicle, but of a thickening and inflammation of the wound. When a puncture had been made this became a papule; lymph squeezed from such a papule and inserted into a second animal gave rise to a like papule, and this, again, might be used for a third animal, but often failed, and the effect could, in no case, be carried on through more than three or four removes. When the inoculation was repeated on an animal on which a previous inoculation had produced such a papule no distinct papule was formed; and, moreover, lymph squeezed from the seat of the latter inoculation produced no effect at all when used for the subsequent inoculation of another animal. There is evidence that the development of the papule was the result of the specific action of the virus. This inference is strengthened by the fact that no such papule was produced by the Lyons Commission when the small-pox matter was inserted into an animal which had previously had cow-pox naturally or artificially, as well as by the fact that when an attempt was made to vaccinate, with vaccine lymph of proved efficacy, an animal on which a papule had been so developed by inoculation with small-pox matter, the vaccination failed, though the animal had never had natural cow-pox or been vaccinated. The specific nature of the lymph of the 'Lyons' papule is held to be shown by the fact that such lymph, when used on the human subject, gave rise to small-pox. On the other hand it has been urged that in this case the virus producing the effect was simply the original small-pox matter used in the inoculation producing the papule and still *clinging* to the wound. This, however, is considered to be disproved by the experience that lymph from a 'Lyons' papule of the second remove also gave rise in the human subject to small-pox. Thus Chauveau and his Commission found that small-pox implanted in the bovine animal gave rise to a specific effect which was not cow-pox but was of the nature of small-pox, though its manifestations in the cow were different from those of small-pox in man."

A few years earlier, in 1860, Martin of Boston, U.S.A., appears to have had a somewhat similar experience, as about fifty persons vaccinated by him from vesicles raised on a cow's udder by inoculation of variolous matter taken from a pock on the body of a man who had died from the disorder were nearly all attacked with small-pox and three died.

Voigt, the director of the Hamburg Vaccine Establishment, in 1881 brought into extensive use, not only in Hamburg but also in other parts of Germany, a strain of lymph of variolous origin. In the early summer of that year he inoculated three calves with lymph obtained from a case of small-pox. In two of these the operation was apparently unsuccessful, in view of which it is of interest to note the fact that all three calves were afterwards found to be insusceptible to vaccination. In the third calf a single vesicle appeared on the site of one out of five incisions made on the left side of the perineum. Voigt adds, however, that this same animal had been vaccinated in one small place in the right hypochondrium (for what reason is not obvious) and at at this point a normal vesicle developed. Voigt does not consider that this fact invalidates the apparent success his experiment, for the reason that, as he says, the lymph derived from what he considers as the variolous source, proved be more potent as regards its observed effects on children and calves than the Beaugency vaccine lymph which he had in current use at the time his experiment was carried out. Both Chauveau and Berthel have, on the other hand, expressed the opinion that Voigt's variolo-vaccine is merely a continuation of the strain of animal vaccine previously employed in Hamburg.

In 1885 Dr. Simpson succeeded in an attempt to inoculate a cow with small-pox lymph obtained from a young vaccinated girl, but as far as I am aware he did not publish the details of this experiment at the time. Dr. Cory, to whom Simpson sent points charged from the cow on the sixth day after inoculation, has recorded the results following on their use in his recent volume on "Vaccination." Three days after receiving the points Dr. Cory employed them at the Animal Vaccine Establishment, Lamb's Conduit-street, for the vaccination of a young male calf. Three out of five insertions made with the lymph resulted in vesicles indistinguishable from those produced by the current lymph of the establishment. A second calf and also a child were therefore vaccinated from the first calf with successful results in each instance, although in the calf only six vesicles resulted from seventeen insertions of the lymph. From this calf a continuous series of calf vaccinations were carried on during a period of six months. With the lymph obtained from these animals, 79 in number, no less than 1247 children were vaccinated, 1174 of whom afforded an insertion success of 98·4 per cent.

Some years later (in 1892) Dr. Simpson, then resident in Calcutta, was again successful in raising a stock of vaccine lymph of variolous origin. Lymph was taken from a small-pox patient on the fifth, sixth, seventh, and eighth day of eruption and each day a young calf was inoculated, the animal having been taken into the small-pox ward for the purpose. The inoculations with the three later lymphs were unsuccessful, but the first calf showed on the sixth day of inoculation three papules on the abdomen and in the groin at points where no punctures or incisions had been made. These on the following day had developed into vesicles. Two of the incisions and one puncture also contained lymph. On the sixth day lymph was taken (whether from vesicles, incisions, or puncture, or all three, is not clear from Dr. Simpson's paper) for the inoculation of another calf, from which, again on the sixth day, a child was vaccinated, the two insertions giving rise in due course to vesicles. From this child the strain of lymph was carried on successfully through nine generations, and Dr. Simpson remarks that each child showed splendid vaccine vesicles, much more typical in every respect than those obtained from the lymph which had been previously in use.

In 1886 and 1890 Fischer, the director of the Institute for Vaccination at Carlsruhe, obtained two strains of variolo-vaccine as the result of inoculation of calves with human small-pox lymph. In the first series Fischer inoculated a young female calf which he took into the small-pox ward of the Pforzheim Hospital for this purpose. Typical vaccine vesicles had developed on the sixth day, the lymph from which was carried on through twelve generations in the calf, after which it was successfully employed for the vaccination of children. Fischer states that the initial experiment of his second series was carried out in the Carlsruhe Institute, but that the animal was placed in a separate stable and that every precaution was adopted to secure freedom from vaccine contaminations. In this calf directly inoculated with small-pox lymph he again obtained, as in his experiments of four years previously, a vesicular eruption having the characteristic appearance of ordinary vaccinia. With lymph taken at the third remove from this calf he vaccinated his own grandson with complete success, and the strain which has now been continued through a very large number of animals has now been brought by Fischer into general use.

Surgeon-Major King, in 1889, being then stationed at Madras, inoculated a young bull-calf with fifth-day small-pox lymph obtained from a child suffering from the disease. On the eighth day after the inoculation a crop of vesicles made their appearance, not at points of insertion, but some little distance away, from the lymph obtained from which another calf was then inoculated. In this calf again secondary vesicles appeared, but in addition vesicles also formed at each point of insertion of the lymph. The lymph stock was carried on through three more generations in calves, the vesicular eruption being now in each instance strictly localised to the points of insertion. With lymph obtained from the fifth calf of the series a number of children were vaccinated successfully. Dr. Simpson reports that from the stock thus established by Surgeon-Major

King 4240 British and native soldiers have subsequently been vaccinated and also a very large number of the native civil population with most gratifying results, the percentages of success being much above that obtained from the lymph previously in use. For reasons which are unknown to me Surgeon-Major King's investigation appears to have been regarded with disfavour by the Government of Madras, by whom he was ordered back to his regiment and deprived of his special emoluments. Subsequently, however, this injustice was repaired by the reinstatement of Surgeon-Major King in his former position as Director of Vaccination in the Presidency.

In May, 1892, Dr. Hime published the results obtained by him in a single experiment on variolation. The lymph employed for inoculation of the first calf was collected from a semi-confluent case of small-pox in a previously vaccinated woman thirty-seven years of age. No details are given as to where the experiment was conducted, but presumably it was the private establishment from which Dr. Hime supplies vaccine lymph, as he makes the statement that "the calf was placed on the ordinary vaccination table used for these animals." A number of skin incisions were made, into which the variolous lymph was inserted. Of these incisions all subsequently healed, being on the sixth day only "detectable to the touch by a slight roughness"; several "pocks," however, developed at points, for the most part distinct from any of the incisions, and material taken from these on the ninth day of inoculation was employed for the direct inoculation of another calf. All the incisions made on this second calf had "taken" on the fifth day, when lymph was collected in tubes and pulp removed by scraping. Some of the latter made into "conserve" with glycerine was sent to Fischer of Carlsruhe, who obtained excellent results with it on a calf from which children were in turn successfully vaccinated. Dr. Hime also himself vaccinated a child with a capillary tube of the lymph in two insertions at each of which points a typical vesicle presented itself on the eighth day.

The largest amount of research work in this direction during recent years is that of MM. Haccius and Éternod (1893), of whom the former is the Director of the Swiss Vaccinal Institute at Lancy, Geneva, where the work was carried out. M. Haccius gives an account of no less than seven successful series of experiments, in each of which a strain of variolous lymph, obtained in the first instance from the human being, was carried on from calf to calf through, in some instances, as many as six or seven removes. The general result was that by the second or at the most the third remove the effect produced was altogether indistinguishable from that which we are accustomed to see in a calf that has been successfully vaccinated. With the lymph of the fifth or sixth remove a number of previously unprotected children were vaccinated with unfailing success. The resulting vesicles could in no way be distinguished from ordinary vaccination vesicles of equal age. The total number of animals employed in these experiments is not mentioned, but from certain statements in M. Haccius's publication one gathers that it was very considerable. It is obvious, therefore, that the Lancy experience as to the small proportion of success to failures is similar to that of other observers. It is worthy of note also that in those animals in which inoculation of variolous matter appears to have been attended with success no definite vesiculation was ever observed at the site of any of the punctures or incisions that were made. The usual result in the first remove from the human being was either a single vesicle or group of vesicular points on the site of a scarification or denudation of the skin. It is particularly stated that every precaution was taken, as, for instance, by the sterilisation of the lancet before each operation, to prevent the accidental transmission of vaccinia.

Dr. Klein, who in 1879 had obtained in thirty-one trials what then appeared to be mere negative results, renewed his investigations in 1892, employing now calves for inoculation experiments instead of milch cows, as in his earlier attempts. Having procured at the hospital ships off Dartford lymph from the vesicles of two cases of confluent small-pox, one at the sixth and the other at the seventh day after appearance of the rash, this lymph was on the same day inoculated by linear cutaneous incisions on two calves at the Brown Institution. The inoculation of one of these calves afforded no indication of success, but on the other calf he obtained a local result in the groin, which, however, consisted not of a distinct vesicle but merely a thickening and redness together with a linear crust at the site of certain of the incisions into which small-pox lymph had been introduced. Lymph pressed from the thickened wound when inoculated into a second calf produced also by the fifth day a like but rather more marked result, while the thickening and redness still further increased as the process was repeated in a third and fourth calf. In none of these animals was there any appearance of vesiculation. At this stage the fourth calf of the series was removed to Lamb's Conduit-street, where Dr. Cory, with material obtained by clamping and scraping the thickened incisions, on the seventh day vaccinated an infant in five separate insertions with complete success. Each of these presented on the eighth day appearances characteristic of vaccinia. Moreover, Dr. Cory, who kept the child under observation from first to last, was unable to detect in the course of the disorder any deviation from the condition of affairs normal to vaccinia. "Crusts" from the arm of this child were preserved and utilised after being mashed up in sterile salt solution for the retro-vaccination of another calf. In due course there resulted in about half of the total number of incisions vesiculation of a character not to be distinguished from that current in the calves vaccinated in the ordinary course at the Lamb's Conduit-street station. Finally, after a lapse of six weeks, Dr. Klein submitted this retro-vaccinated calf and other calves vaccinated from it to the test of a further and thorough vaccination with current calf lymph and with the result that all these animals entirely resisted vaccinia. I have learnt privately from Dr. Klein that in his former (1879) experiments on cows he in more than one instance obtained results somewhat similar to those witnessed in the calf on which his more recent successful inoculation was performed. He suggested at the time the advisability of attempting a transference to a second animal, but Ceely, who was superintending the experiments, insisted on the necessity of obtaining a vesicle in the first animal inoculated as the only criterion of success and the suggestion was therefore overruled. For his own satisfaction, however, Dr. Klein endeavoured to vaccinate one of the cows which had shown some local reaction, but entirely without result, the animal apparently being immune.

Of my own experiments the most successful series may briefly be described as follows: with variolous lymph (contained in two capillary tubes) taken on July 30th, 1892, from a vaccinated girl, aged sixteen years, at from the fifth to the sixth day of the eruption of discrete small-pox I inoculated on Aug. 11th a cow-calf (A) about six weeks old by 32 linear incisions and 2 superficial scarified patches made on the abdomen. On Aug. 13th (the third day) this calf presented nothing but a slight scab over the scarified patch. On Aug. 15th (the fifth day) some of the incisions were somewhat red and elevated, more particularly at several definite points which tended to be vesicular. At this date, on the inner aspect of each thigh and distant in each instance from incisions or scarifications, was a crop of shotty and incipiently vesicular pimples. On Aug. 17th (the seventh day), having clamped 3 of the incisions, including those with the quasi-vesicular appearance, I removed the lymph with the crusts by scraping and used the material for the inoculation on this date of calf B. The accessory incipient vesicles I left untouched. From first to last calf A never exhibited any appreciable rise of temperature or indisposition of any sort. On the ninth day the linear incisions, the cross scarifications, and the accessory vesicles of calf A were in their decadence and in a few days more the whole process was at an end. More than a month later—namely, on Sept. 22nd—I vaccinated this calf A in 23 linear incisions with calf lymph obtained from the Animal Vaccine Establishment. The result was absolutely negative.

On Aug. 17th, with the scrapings obtained the same day from calf A, I inoculated a cow-calf (B) two months old in 56 linear incisions on the abdomen. On the third day every one of these incisions was distinctly raised and bordered by a delicate pink flush. On the fourth day (Aug. 20th) all incisions had evidently taken, the areola about each being now well marked and about one-eighth of an inch in width, but there was no definite vesiculation. At this date, after clamping, scrapings were taken from certain of the incisions for further experiment. No accessory vesicles appeared in this calf, which, along with calf A, was vaccinated on September 22nd in 17 linear incisions with calf lymph obtained from the Animal Vaccine Establishment. The result, as in calf A, was absolutely negative.

On Aug. 20th, with scrapings taken the same day from calf B, I inoculated a small cow-calf (C), seven weeks old, in 27 linear incisions on the abdomen. On the

fourth day (Aug. 23rd) every incision had "taken" and in most of them there was evidence of commencing vesiculation. Two days later (Aug. 25th) vesiculation was distinct in several of the incisions. At no time were there any accessory vesicles. This calf also was vaccinated (Sept. 22nd) with calf lymph from the Animal Vaccine Establishment. Again the result was altogether negative.

Thus far I have obtained an undoubtedly successful result in one series only out of four attempts, but I have at any rate been able to satisfy myself that it is possible to variolate the calf, and, further, that the result obtained in the first instance may become greatly modified in the course of successive removes; and, again, that animals which have been thus treated are no longer susceptible to vaccination.

I may, perhaps, mention here that all my experiments were conducted at the Brown Institution to avoid any possibility of contamination with vaccinia; that, as a further precaution, new scalpels were used, which were invariably first carefully sterilised in a flame; that before and after use the table was thoroughly washed with carbolic acid and hot water and during the intervals of use kept exposed to the open air.

The Royal Commission on Vaccination, in the section of their report dealing with the question of the relationship of variola and vaccinia, shows that the various series of inoculation experiments, of which I have given a brief account, fall into one or other of three categories. The first category includes the experiments of Thiele, Ceely, Badcock, Voigt, Haccius and Eternod, King, Simpson, Hime, and others. In these experiments "inoculation of small-pox matter into the udder or adjoining parts of the bovine animal gave rise at or near the site of inoculation to a vesicle either identical in visible characters with the ordinary vaccine vesicle produced by inoculation with the matter of cow-pox or to a vesicle the features of which, while not corresponding wholly with those of a perfect vaccine vesicle, so closely resembles it as to justify the recognition of the vesicle as a vaccine vesicle. Also it includes experiments in which, though the local result had not the characters of a perfect vaccine vesicle, yet lymph from it when carried through a second or third remove in the cow or calf presented results fully manifesting those characters and when again transferred to man gave results indistinguishable from the ordinary vaccine vesicles." In the second category are placed the experiments of Dr. Klein and myself. In no instance did either of us obtain any appearance of vesiculation in the animals directly inoculated with small-pox virus, although the appearance of the eruption tended to resemble more and more that typical of vaccinia the further the remove, through a series of calves, from the original strain. In the third category are included the practically negative results of the Lyons Commission obtained by Chauveau and his fellow-workers. A brief account of these has already been set out.

With the exception, then, of Martin and of Chauveau and his colleagues of the Lyons Commission all the observers mentioned claim to have obtained positive results—in a certain number of their experiments at any rate—as regards the production of typical vaccinia after one or more removes as the result of variolation of the cow or calf. By no one, apparently, has success been attained invariably, but it is among the experiments of the earlier observers especially, who made use for the most part of heifers and milch cows, that the largest proportion of abortive attempts are to be met with. Subsequent experience has shown that success is much more likely to be attained if calves be used instead of heifers or cows. In this way, perhaps, Chauveau's somewhat anomalous results may be in part explained.

With reference to recent experiments on variolation of the calf it is worthy of note that, as previously mentioned, different observers have obtained local effects in that animal which in different calves of a series have varied considerably. The final result has, however, after a greater or less number of removes from calf to calf, been invariably the same—namely, a local vesicle is produced which by no means at our command, such as the appearance and course thereof or the protective power of the lymph derived therefrom, is distinguishable from true vaccinia.

Although practically there is unanimity of opinion among those who have worked at this subject it must be confessed that, seeing the conditions under which they were carried out, many, particularly of the earlier experiments, are of little worth. Some of the main objections are based on the fact that experiments on this subject have almost without exception been performed in establishments devoted to the continuous cultivation of vaccinia, on the use concomitantly of vaccine and of variolous lymph on the same animal, and on the want of care as to the cleanliness and freedom from vaccine contamination of lancets and "points" used in the experiments. Objection of similar sort against the variolations of the calf which have been achieved in recent years is hardly valid. In some of the more recent cases, at least, special precautions have been taken to ensure that the instruments and table were sterilised and to render the environment of the animal such as to afford no likelihood of the communication of vaccinia. Most especially was this so as regards Dr. Klein's investigations and my own. The number of successful cases which have been recorded is now so large that it is difficult to believe that sources of fallacy of the above sort should have been present in every instance, and it is therefore well-nigh impossible to resist the conclusion that a change of small-pox into vaccinia must really have come about.

Nevertheless there are found even at the present day those who, like Juhel and Dupuy (1894) and Layet (1895), maintain the essential duality of variola and vaccinia. It is, however, difficult to understand how the results obtained, by the last-mentioned especially, can bear the interpretation he would place upon them, seeing that he obtained as the result of inoculating heifers with small-pox lymph a vesicular eruption, the lymph derived from which reproduced the disease on other heifers. Moreover, subsequent vaccination of all his series of animals was either abortive or wholly without result.

Hervieux (1895), the director of the Vaccine Institute attached to the Académie de Médecine, takes up a similar position to that of Layet and his collaborators, Le Dantec and Benech. He asserts that the only point of similarity between variola and vaccinia which has been brought forward by those who believe in the relationship of these disorders is the likeness between the vesicles which are found in either case and denies that this point forms any argument in favour of their identity. He also considers that the use of lymph of variolous origin is fraught with danger, and so doubtless it may be when that employed is derived—as in Chauveau's and Martin's cases, for instance—directly from the animal first inoculated.

If, as I believe, it can be conclusively proved that small-pox lymph, by passing through the system of the calf, can be so altered in character as to become deprived of its power of causing a generalised eruption, while inducing at the site of inoculation a vesicle indistinguishable from a typical vaccine vesicle, and, more important still, if it be shown that when transferred again to man it has, by such treatment, completely lost its former power to produce a general disease, it may fairly be asserted that cow-pox—or rather that artificially inoculated form of the disease which we term vaccinia—is nothing more nor less than variola modified by transmission through the bovine animal. Perhaps the most reasonable interpretation of such results may be that small-pox and vaccinia are both of them descended from a common stock—from an ancestor, for instance, which resembled vaccinia far more than it resembled small-pox. It is conceivable, indeed, that the seeming vaccinia obtained in the calf by inoculation of small-pox matter into that animal may, after all, be but a reversion to an antecedent type; and in this connexion we may call to mind a fact of universal experience—namely, that vaccinia, however it may have arisen in the past or is made to appear in the present, exhibits little tendency to "sport" (as, for instance, by manifesting a "generalised eruption") in the direction of small-pox.

Mr. Picton and Dr. Collins, in their addendum to the report of the Royal Commission on Vaccination, lay much stress on the want of "evidence to show that inoculation of the pox of the cow on the human skin has ever produced small-pox." Variola and vaccinia may, nevertheless, have a common ancestry, since it is not unlikely that variola may have departed widely from the original type and have gained an exalted virulence by repeated passage through man under conditions favourable to its propagation and activity. If this evolution of the disease has, in fact, taken place variola may have suddenly reverted under greatly changed conditions (as, for instance, implantation on the bovine animal) to an ancestral type. But the reverse process—i.e., sudden "sport" of vaccinia in the direction of small-pox—is not to be expected. It is most unlikely that a less differentiated form (cow-pox), also emanating from the common ancestral stock, should attain to the most exalted virulence in a single individual and *per saltum* declare itself as small-pox, as the dissentient Commissioners insist that it ought to do.

DETAIL IN SURGERY.

BY T. PRIDGIN TEALE, M.A. OXON., F.R.C.S. ENG., F.R.S.,
CONSULTING SURGEON TO THE LEEDS GENERAL INFIRMARY.

I.—OPERATIONS FOR HÆMORRHOIDS.

MY life as a surgeon has been long enough to have seen nearly the whole series of methods by which hæmorrhoids have been dealt with—in modern times, at any rate.

In the earlier operations nitric acid was employed and was applied, without anæsthetic, manacles, or Clover's crutch, to hæmorrhoids protruding from the anus as a result of straining over hot water in a night commode. As an improvement in the nitric acid method I was taught by my father to introduce into the rectum one of Weiss's dilators of the female urethra and then after this preliminary step to apply the acid to the diseased portion of the anal canal whilst thus dilated. Two advantages were gained by this modification: firstly, the freedom of the surgeon from dependence upon the goodwill of the hæmorrhoids for their convenient extrusion; and, secondly and mainly, the thorough dilatation of the sphincter, with its security against subsequent spasmodic contraction upon a mucous membrane which was often both protruding and cauterised. This plan was probably a reaction from an older method of ligature in which the strangled piles had to slough off and which not rarely ended in pyæmia.

My next stage of experience was with Smith's clamp and cautery. To this I held for some years, but the method did not entirely satisfy me, as occasionally there was bleeding into the rectum from the seared stump. About this period my colleague Mr. Walter Brown returned to Leeds as resident surgical officer to the infirmary. He told me of the operation in use at the South London Hospital, where he had recently filled a similar post, in which the hæmorrhoid was transfixed at its base, very firmly tied, and cut away close to the ligature. I thenceforth adopted the plan and made use of it until it was superseded in my practice by what I consider to be the far more satisfactory operation which I have now to describe. To this operation, which I have now used exclusively for the last fourteen years, I was led by four main considerations. 1. The manner in which hæmorrhoids present themselves externally, becoming as accessible as any ordinary growth or tumour on the surface of the body on dilatation of the sphincter, a step I had from a very early time been accustomed to take as a preliminary to all operations on the lower part of the rectum. 2. The method of Coates, which had much impressed me. It consisted in clamping the hæmorrhoid, in cutting it off close to the clamp, and, as a final stage, in closing up the raw edges and bleeding surfaces by ligatures with the clamp still *in situ* instead of arresting the bleeding by cautery. 3. The establishment of a further extension of excision of hæmorrhoids by Whitehead of Manchester, who proposed the complete excision of the anal ring of hæmorrhoidal mucous membrane, the bleeding being controlled by ligature and the union of the divided margins being attained by suture. 4. The development of the convenient volsella forceps which I had devised for holding down the os and cervix uteri when dilating and curetting the uterus and which command a complete mastery over the hæmorrhoids during excision. These four considerations chiefly influenced me in deciding to depart from the procedures in vogue at the time.

Let me now give a description of the details of the operation itself: 1. Believing dilatation of the sphincter ani to be, along with tooth-drawing and reduction of dislocation, the kind of proceeding in which chloroform is attended with more than its usual risk *I would urge ether emphatically as the anæsthetic.* 2. The lithotomy position, maintained by manacles and Clover's crutch. 3. Commence, as a matter of course, by dilatation of the sphincter ani, which not only brings the hæmorrhoids into view but is a security against spasmodic disturbance of the wound subsequently to the operation. 4. Grasp the most prominent hæmorrhoid at each extremity by a volsella forceps and hold it securely during the operation. This gives the surgeon perfect command both during excision and whilst completing the operation by suture. 5. Excise the hæmorrhoid with curved scissors by marking out and partially dissecting off a shallow flap, firstly, on the mucous membrane side and then on the cutaneous side and then excise the hæmorrhoidal mass. 6. Having tied any obviously pulsating vessels, bring the two sides of the wound together by continuous suture in the following manner: commencing about ½ in. from one end, let a continuous suture of fine catgut be passed rather deeply so as to bring the whole surface of the wound together and to control any oozing that may be taking place. Terminate this suture about ½ in. from the other end of the wound but neither tie it nor fix it anywhere. On the contrary, secure it for the time being only by clip forceps, after having drawn it tightly enough to stop all hæmorrhage. 7. In like manner deal with a second or even, if necessary, a third hæmorrhoid, taking care to leave about ½ in. of mucous membrane between each wound. 8. Finally, remove the clips from the sutures, which are then cut, leaving about 1 in. protruding at either end. 9. As a rule the sutures disappear and do not need removal. If they do not they can be pulled out without difficulty at the end of a few days, having no fixed point. 10. The after-dressing is practically *nil*. Some cotton wool is placed between the buttocks to absorb any oozing of blood or serum, but *no lint or other dressing is introduced into the anus.* This is absolute and *de rigueur*.

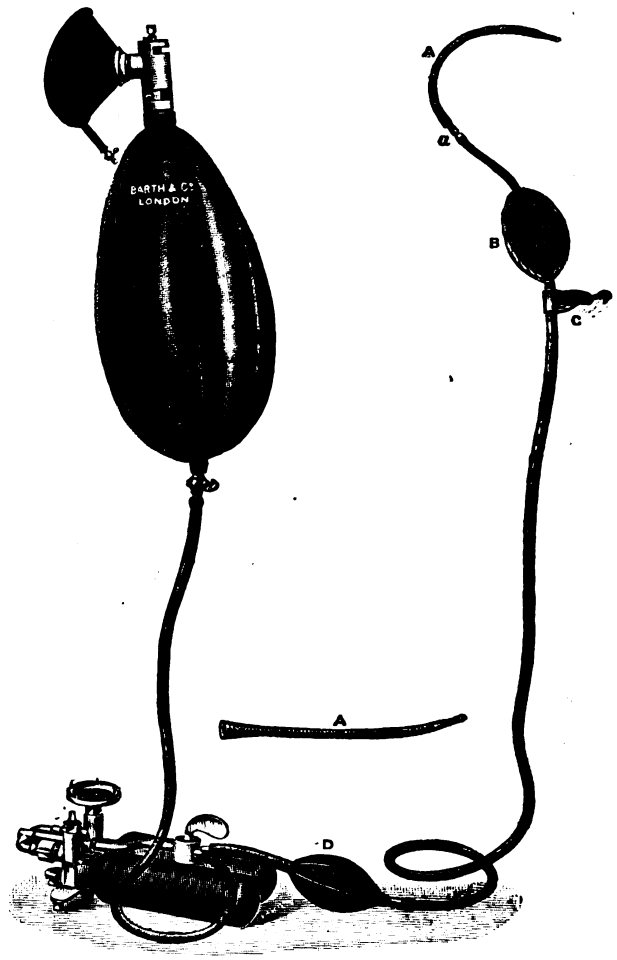
Advantages claimed for this method.—Having had many years' experience of nitric acid, of clamp and cautery, and of tying with excision, whilst I have had fifteen years' experience of the method just described, I feel that I may claim for the latter the motto, "Cito, tuto et jucunde." *Cito*, if not in the actual operation, at any rate in rapidity of recovery; *tuto*, in the absolute security against hæmorrhage and the increased security against septic accidents—not unknown in the old days of ligature—owing to healing by first intention; and *jucunde*, by reason both of the lessened after-pain and of the greatly reduced tendency to retention of urine, the after-pain being often capable of being reduced to insignificance by very careful soaking of the wound before stitching by a strong carbolic solution (1 in 30).

I am told that retention of urine is common, indeed, almost expected as a matter of course, where hæmorrhoids have been removed by ligature or by cautery. It is comparatively rare after the operation I have been describing, which has also the advantage over Whitehead's of being free from the risk of subsequent cicatricial stricture and is at the same time equally applicable to any degree of hæmorrhoids, however extensive.

One may ask how it came about in former days that cautery and ligature were used and not excision. Purely, I believe, from fear of hæmorrhage after operation, for in days when dilatation of the sphincter as a preliminary to removal of hæmorrhoids was practically unknown and efficient volsella forceps for holding the cut surface in view were uninvented the danger was a very real one. An open wound with a bleeding vessel inside a rectum guarded by a contracted sphincter used sometimes in those earlier days to produce a hæmorrhage at once dangerous and concealed. It was to meet this evil that ligature of the whole hæmorrhoid, destruction by nitric acid, and the method of clamp and cautery were invented. But now that we dilate the sphincter, that we have means of holding any amount of hæmorrhoid in view, that we arrest the bleeding of visible vessels by catgut ligature, and can bring the cut surfaces into firm apposition by a suture which either is absorbed or can be pulled away after a few days, the need for these more primitive details seems to have not only lessened but entirely disappeared.

Leeds.

A METHOD OF PROLONGING NITROUS OXIDE ANÆSTHESIA IN DENTAL PRACTICE.[1]



BY HARVEY HILLIARD, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT ANÆSTHETIST TO THE DENTAL HOSPITAL OF LONDON.

ANÆSTHETISTS are agreed that nitrous oxide would be a perfect anæsthetic for dental procedures but for the brevity, after the removal of the face-piece, of the available anæsthesia produced by its inhalation. Hitherto, therefore, only operations of the shortest duration could be attempted when nitrous oxide has been employed, while in those cases

[1] A paper read before the Society of Anæsthetists on March 17th, 1898

requiring an anæsthesia of two to three minutes' duration the nitrous oxide has to be in the vast majority of cases supplemented with the use of ether. Since, however, ether is so liable to be followed by unpleasant after-effects, is so pungent in odour that it clings about the operator's room all day, and since so much preparation of the patient is necessary before the drug can be administered, it is often deemed advisable to perform the operation at the patient's own house in order to minimise these many disadvantages. With nitrous oxide, however, we have practically none of these drawbacks. After-effects, if present, are of such a transient nature that a patient can walk home comfortably within a few minutes of the administration; the gas is without odour and is not unpleasant to inhale; and, moreover, little or no preparation is necessary prior to its inhalation. It is obvious, therefore, that if an anæsthesia of several minutes' duration, after the removal of the face-piece, can be obtained with nitrous oxide, by whatever means, this agent will be used with increasing frequency, and that it will only be supplemented in those cases where an unusually prolonged narcosis is required, as, for instance, in extensive immediate torsions, regulations, and multiple extractions. Up to the present time the means adopted for prolonging the anæsthetic effect of nitrous oxide have been very imperfect, being based for the most part upon the principle of preventing the elimination of the gas, thereby obtaining merely a slightly prolonged anæsthesia; but by preventing this elimination we must prevent or impede respiration also. Such methods, for instance, as pushing backward the lower jaw together with the tongue, thereby closing the orifice of the larynx, or by passing a sponge upon a holder backwards and downwards into the pharynx, produce very marked congestion and cyanosis, with jactitation—in fact, the signs of impending asphyxia. The patient under these circumstances is in a dangerous condition; there is great engorgement of the venous system and right side of the heart, and should there be present any degree of valvular cardiac disease the heart muscle might be unable to cope with the extra strain thrown upon it and the administration might possibly terminate fatally. In almost every reported case of death occurring during the exhibition of nitrous oxide it has resulted from obstructed respiration and consequent asphyxia. We are always very careful, therefore, when administering the gas to patients suffering from valvular disease of the heart not only to ensure perfect freedom of respiration, but also to allow a due admixture of air or oxygen, in order that all jactitation, cyanosis, and cardiac engorgement may be avoided. There is also another grave objection to this mode of prolonging nitrous oxide anæsthesia by preventing elimination, for, as pointed out above, it produces much congestion and cyanosis and this relieves itself locally by increased hæmorrhage from the gums and empty tooth-sockets, so that the patient's mouth rapidly fills with blood, whereby the operator is much hampered or even forced to abandon the operation, as there is not sufficient time for systematic sponging. Further, unless the patient's head be kept in such a position that the lower jaw and floor of the mouth form a sort of reservoir for the collection of this blood, it will gravitate backwards and at the first inspiration (which is always of unusual depth) it will probably be sucked into the air-passages, necessitating immediate tracheotomy to save the patient's life. It should always be our aim, therefore, to maintain the patient's head in the most convenient position for the operator consistent with the safety of the patient, but where the above methods are adopted the operator has to work in an unfavourable position, and thus the ultimate gain in time is practically of no value owing to the increased difficulties of the extractions.

The late Mr. Clover, aware of the advantages of obtaining a prolonged anæsthesia with nitrous oxide in dental surgery, made experiments with a "nose-piece," by means of which he hoped to continue the administration of gas and thus to prolong its anæsthetic action during operations on the mouth after the ordinary face-piece had been removed. To this end, when the patient was fully anæsthetised, he fitted over the nose a small accessory inhaler, to which nitrous oxide was supplied by means of a stopcock and tube communicating with a gasometer. He expected that sufficient gas would be inspired through the nose to maintain an anæsthesia already produced by the ordinary method and thus to enable the surgeon to undertake longer operations upon the jaws than could otherwise have been attempted except under the influence of ether. The results did not prove sufficiently satisfactory and Mr. Clover abandoned the idea. The apparatus was difficult to keep properly adjusted, so much air was breathed through the mouth that the anæsthesia was uncertain, and finally the gas could not be supplied at sufficient pressure to obviate this evil without being likely to cause damage to the olfactory region, the frontal or even the maxillary sinuses. Having found that prolonged administration of nitrous oxide for ordinary surgical procedures was attended with the best results, I attempted to devise a method whereby this anæsthetic could be employed in extensive operations in dental surgery, and I soon discovered that the only channel for the convenient administration of the gas after the removal of the face-piece was by means of a tube passed along the inferior meatus of the nose. First, a small-sized celluloid female catheter seemed to be the most suitable instrument for this purpose; but this was discarded owing to its rigidity, for a surprisingly large

A, Nasal tube; a, Vulcanite nozzle. B, Netted bag. C, Hook for fixing to head-piece of chair. D, Expansion bag.

number of patients are found to have a deviated nasal septum, an unusually arched palate, causing a corresponding curve of the floor of the inferior meatus, or much depressed inferior turbinated bones covered with hypertrophied mucosa which would be considerably damaged by the forcible passage beneath them of a rigid instrument. Next, a No. 7 (English) soft rubber male catheter was tried. This answers admirably, except that it takes longer to pass and is liable to be blown out by the pressure of gas supplied through it combined with the patient's expiratory efforts, and also on account of its flexibility it is more difficult to keep out of the operator's way without kinking. Lastly, a soft gum elastic silk tube was employed. This tube is equal in diameter to a No. 7 catheter; it is six inches in length and its distal end is made like an *à boule* male catheter. This is solid up

to the orifice, which is situated half an inch from the point, the proximal end being expanded to receive the conical attachment of tubing, in connexion with the portable steel cylinders in which the gas is usually stored. Two of these cylinders are connected up in the usual manner and fitted with a stopcock which has been made to my design by Messrs. Barth and Co. It is a tube of inlet to a stopcock chamber which is screwed into the cylinder connexion and lies in the space between the cylinders so as to be out of the way. This chamber is fitted with a two-way stopcock, the tap of which is an elongated broad arm, so that it can be easily turned by the foot. From the chamber lead two tubes of exit. The tap is so arranged that when it is turned on to either of the two exit tubes the arm lies over that tube through which the gas will flow when liberated from the cylinders by means of the ordinary foot-key. The whole gas supply can thus be entirely controlled by the administrator's foot. The exit tubes, like the other parts of the stopcock, are made of brass, are placed at an angle, and are an inch long, with bulbous ends so that rubber tubing can be easily slipped over them. To one is attached a Dr. Hewitt's gas inhaling apparatus; to the other the connexions of the nasal tube, which consist of the following:—A small stout rubber "expansion" bag, intended to regulate the usually irregular flow of gas from the cylinders. This is fixed by one end to a stopcock exit, the other extremity being connected by tubing to a thinner and large rubber bag covered with netting, which is continued as a small tube bearing a conical vulcanite nozzle, fitting into the funnel-shaped extremity of the nasal tube proper, A. This second bag is fixed by a hook to the head-piece of the dental chair and by noticing its degree of expansion the anæsthetist is enabled to tell whether his patient is getting a sufficient supply of gas to maintain anæsthesia.

The administration is conducted in the usual way until the patient has lost conciousness; then, taking the precaution that the ordinary gas bag is full, the stopcock having been turned on to it, and choosing the end of an inspiration, the face-piece is removed, the nasal tube is rapidly passed (this can be done during a single expiration), the face-piece is reapplied, and the stopcock is turned, so that the gas now only flows through the nasal tube; at this stage the inhalation is continued by both nasal tube and face-piece up to full anæsthesia; the face-piece is now finally removed, the operation is begun and narcosis is maintained by the nasal tube alone. To prevent the return of consciousness the "netted bag," B, must be kept fully distended, the gas being supplied at considerable pressure. In a typical case the patient is but slightly cyanosed and there is little or no jactitation (as he inhales sufficient air through the mouth and the free nostril), but the conjunctival reflex is absent. Should, however, he be of the type which requires but little gas, or if for any reason the mouth be considerably obstructed either by sponges or by the operator's hand, the nasal septum being at the same time markedly deviated towards the free nostril, the intake of air in proportion to the intake of gas is so lessened that deep cyanosis, jactitation, and even opisthotonos are produced. If, on the other hand, more gas is necessary to maintain anæsthesia the free nostril can be closed by the anæsthetist's finger or even the mouth can be partially obstructed by inserting a sponge. The extremity of the nasal tube is made to impinge on the posterior pharyngeal wall in order that the flow of gas may be directed by means of the orifice in its under aspect immediately over the upper opening of the larynx, therefore great care must be taken not to permit a very free supply of gas from the cylinder, as by so doing an over-dose would easily be administered.

With this apparatus I have succeeded in keeping patients fully anæsthetised for operations lasting over four minutes and have only then discontinued the administration because the operation has by that time been completed, and not because the anæsthesia could not be further maintained by this method. The tube has been employed in over 100 cases, in 2 of which the operation of tapping and draining the antrum of Highmore was performed and in 1 immediate torsion was exerted upon a lateral incisor tooth. But in a series of 30 consecutive cases of tooth extraction amongst patients of both sexes of which I have made notes the average period of anæsthesia was roughly 1 minute 50 seconds. These cases were chosen as suitable ones for the employment of the tube on account of the necessary extractions being very numerous or appearing to be of unusual difficulty and in only 1 case had the operation to be curtailed; in this case the hæmorrhage from the gums was so profuse that on this account, after 12 extractions, the operation had to be stopped as no sponges were at hand. The anæsthesia in this case lasted 2½ minutes. The tube is easily kept out of the operator's way by being slipped over and behind the patient's ear. There is no fear of conveying sepsis, for the tube can be sterilised with the greatest ease and in hospital practice I am in the habit of employing two, which are used alternately, so that one can be soaking in antiseptic solution while the other is in actual use. The nostril on the same side as that on which the anæsthetist stands is the more convenient for the passage of the tube, but as the nasal septum is not infrequently deviated to this side one is compelled occasionally to pass the tube along the opposite nostril. The only absolute contraindications to its use are marked hypertrophy of the nasal mucosa or adenoid growths in the naso-pharynx, in either of which cases troublesome hæmorrhage would result from injury to these tissues. Great care must be exercised in passing the tube so that it can be felt to impinge on the posterior pharyngeal wall, as it is easy to pass it too far and so to inflate the œsophagus and set up swallowing movements and vomiting. Even where due caution is practised vomiting seems to be less uncommon than in ordinary nitrous oxide anæsthesia and for this reason patients should be recommended to abstain from food for two or three hours before the administration. If this precaution be taken and one is careful also that the patient swallows no blood, unpleasant after effects will be very rarely met with.

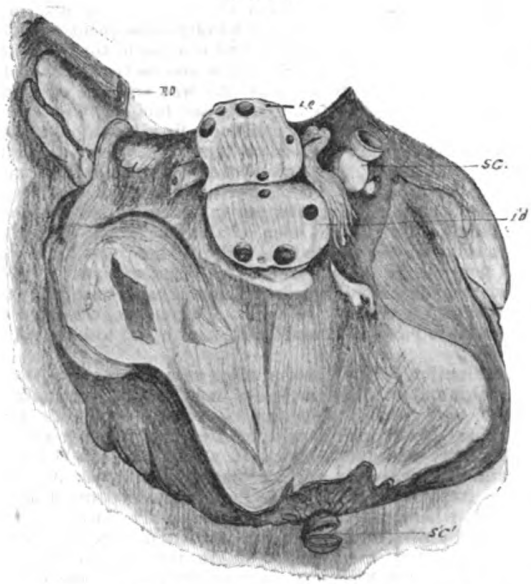
In conclusion I claim for this apparatus that it will render the employment of ether unnecessary in dental surgery; that owing to its small bulk and great portability it is more convenient and economical as regards the quantity of nitrous oxide used than any other apparatus employed with the same object; and, finally, that in skilled hands it is free from the risk of damage to the nose, the naso-pharynx, or the mouth and is without danger to the patient.

Welbeck-street, W.

A CASE OF OVARIOTOMY IN WHICH A PRIMARY OVARIAN AND SIX OMENTAL DERMOID CYSTS WERE REMOVED.

BY J. LACY FIRTH, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE BRISTOL GENERAL HOSPITAL.

A WOMAN, aged thirty-eight years, was admitted under my care at the Bristol General Hospital on Sept. 18th, 1897, complaining of abdominal pain and swelling. She had been married fifteen years, but had had no children and no miscarriages. Menstruation had been regular with one exception throughout her married life. The exception was that she missed three periods a year after marriage. She had at that time a three months' illness, which she called "inflammation of the bowels." The pain then was chiefly in the right iliac fossa. A month before admission the patient had been suddenly seized with abdominal pain when walking in the street. It was in the hypogastric and left iliac regions chiefly. With the pain came abdominal swelling. The swelling had steadily increased since. Vomiting had been frequent and she had lost flesh and strength rapidly. Careful inquiry elicited that from time to time during some months before the onset of her present illness she had suspected that the lower part of the abdomen was enlarging. She had had diarrhœa also, though not severely, for three weeks. On admission the patient was sallow and greyish and she looked anxious. The temperature was 100° F. and the pulse was 95. The abdomen was symmetrically distended in the lower half from the symphysis to a level of 2 in. above the umbilicus. The distended region was moderately tense, very tender, especially in the left iliac region, dull on percussion, and yielded a slightly marked thrill when tapped. There was a corona of resonance around it in the flanks and epigastrium. It was central. A softish mass, slightly moveable upwards and downwards, was felt lying across its upper and front part. It was thought to be an adherent coil of intestine (probably it was the thickened omentum containing secondary dermoids).



There were no signs of ascites. There was no trouble with micturition. Vaginal examination revealed a long conical cervix with nulliparous os. Through the anterior fornix the body of the uterus was felt in front of the swelling. On each side of the uterus there was a sense of tensity and fluctuation was detected bimanually. Through the mucous membrane of the right lateral fornix three small, hard, and conical eminences were felt, two close together and the other a little posterior in the same line. These bodies were quite fixed. They were felt with extreme distinctness. On rectal examination the same hard eminences were felt through the anterior wall. These hard eminences were regarded as dermoidal teeth, which they subsequently proved to be. The only other view which could be entertained was that they were fœtal bones. Against that view the history of regular menstruation and the absence of any signs of pregnancy or history of these signs or of spurious labour afforded strong arguments. It is not often that a dermoid tumour can be diagnosed with as much confidence as in this case. Six days after admission, the patient's condition having remained stationary, laparotomy was performed (Sept. 24th). Mr. J. Freeman kindly gave ether and Mr. Rayner and Mr. Druitt gave me much valuable assistance during the operation. The median incision which was made bled more than usual, perhaps by reason of the subjacent adhesions. There was some difficulty in defining the peritoneal cavity, the tumour being adherent to the parietes beneath the incision. A Spencer Wells trocar was passed into the cyst as soon as its anterior surface had been exposed and yellow, fatty-looking fluid immediately flowed through it. The cyst could not be pulled out of the abdomen in the least degree, owing to universal adhesions. To complete the emptying the trocar aperture was enlarged and the patient was turned on her side for the fluid to escape through the rent. A mass of hair and sebum of the size of a bantam's egg was removed with the finger. Then the separation of the cyst wall was begun. The hand was freely and frequently inserted into the cavity of the cyst for the purpose of defining its wall. Deep down in the pelvis a mass of bone was felt projecting somewhat conically into the cyst cavity and teeth were felt fixed to its margin. The abdominal incision was carried 1½ in. above the umbilicus. The omentum was peeled from the anterior and upper surface of the cyst. In the omentum, as it was peeled off, were found three ovoid smooth tumours, the largest of the size of a large plum, the smallest of that of a cherry, and the omentum itself was very thick and indurated. Beneath the omentum a coil of small bowel about a foot long had to be peeled off. The most difficulty was experienced in separating the adhesions on the right side. The cæcum and the appendix were adherent and the latter was stripped from its mesentery in the process of separation. Subsequently the appendix was removed as it was not thought safe to leave it in a denuded state. Hæmorrhage caused anxiety on one or two occasions. Several times there were as many as 18 Spencer Wells forceps on different bleeding areas at the same time. At this stage nothing like a pedicle could be seen. Later, when the lateral and posterior adhesions had been freely divided, the deeper part of the tumour with the uterus, tubes, and ovaries attached could be drawn up nearer to the surface, and this made the final steps of the removal much easier. With the finger the posterior surface of the uterus in Douglas's pouch was separated. The cyst appeared equally blended with both broad ligaments. Each ligament was therefore divided and ligatured in successive segments close to the uterus, beginning on the left side with the Fallopian tube. In the end the cyst was extracted complete with the exception of a square inch which was removed later. The right ureter was exposed for two inches as it crossed the brim of the pelvis. It was as thick as a large finger. The three omental dermoids were next removed, with the portions of omentum containing them. From five to eight minutes were spent in flushing out the peritoneum with hot sterilised saline fluid. This fluid flowed away clear at the end. The pelvic cavity was carefully sponged and a Keith's tube was lodged in it. The wound was closed with one row of sutures passing through all the structures of the abdominal wall. The operation lasted nearly two hours. At the end the patient was in a state of severe shock. She was cold and had a rapid, thready pulse. An enema of brandy was given at once on the operating table. This was at 4 P.M. At 10 P.M. reaction had set in; the temperature was 100·6°, the pulse was 121, and the respirations were 34. For the next three days the patient's condition was somewhat critical. There were frequent vomiting and great restlessness and severe abdominal pain with flatulence and hiccough. Under appropriate treatment her condition gradually improved so that at the end of a week anxiety was over. The day after the operation about a drachm of oily fluid, like butter melted, was extracted from the drainage-tube. Oily fluid similarly continued to escape for five days in diminishing quantities. On the sixth day a small quantity of clear serum only escaped and the tube was left out.

The abdominal sutures were removed at the end of a fortnight. At this time and upon every subsequent examination two small swellings were found to exist in the abdomen. They were situated about 2 in. below and to the right of the umbilicus. The more distinct one was smooth, spherical, moderately hard, slightly moveable and tender, and of about the size of a bean and seemed to be fixed to the posterior abdominal parietes. Close below it was a somewhat similar swelling but less distinct and of more elongated form, more like an almond. These bodies were felt again three months after the operation, when the patient came to see me as an out-patient. They were then unaltered, except that their tenderness had disappeared. I believe these swellings were small peritoneal dermoids which had been left behind. The patient was discharged from the hospital in an excellent state of health at the end of five weeks. Three months later she was found to have maintained that health and to have gained flesh.

Examination of the tumour after removal showed it to be unilocular and about as large as a man's head. The interior of the wall had a covering of coarse skin with large sebaceous gland orifices and bristles over the conical projecting bony mass mentioned. In the other parts there was no skin. The external surface was very shaggy. Attached to the front were the ovaries and tubes, separated by an interval where the uterus had been. The ovaries were exposed by dissecting from the front and were laid open. Each presented numerous cysts in the peripheral region (oöphoronic), fairly uniform in size, with a diameter of ¼ in. to ½ in. The right ovary was the larger of the two and irregular in shape. The hilum of each was very dense. The right ovary could easily be peeled from the dermoid cyst, but one surface of the left ovary was in organic continuity with it. This ovary, the left, was almost normal in shape, though somewhat flattened. It was the superior surface of the left ovary which was firmly united to the cyst wall. The union of the two structures in this region was so firm and intimate that they could only be separated without destruction by using the scalpel. Even when the ovary had been shaved off flush with the cyst wall there was still left a whitish layer on the cyst, with the outline of the ovary and an appearance of ovarian tissue. I have described this union of the cyst and ovary with a little detail because it is unusual to find a large dermoid arising in an ovary and leaving that ovary almost normal in appearance and size. It raises a doubt as to the place of origin of the dermoid cyst, suggesting that it may have arisen from a fœtal relic near but not in the ovary. But the intimate union of the ovary and the cyst makes it almost certain that the cyst is of oöphoronic origin, as ovarian dermoids are usually supposed to be. The cyst in all probability from the first grew from the surface outwards and so produced a minimum effect upon the ovarian stroma. The Fallopian tubes in the specimen were easily exposed by a little dissection above the ovaries. They were convoluted but were normal in calibre and length and empty (Fig. 1). It is clear that the tumour from the left ovary grew to the right behind the uterus and behind the right broad ligament. Two portions of omentum were removed, one small piece, containing one cyst, and a larger piece (Fig. 2). Careful examination of this larger piece showed that there were in all five cysts firmly embedded in its substance. The largest one was of the size of a large plum, tense and thick-walled, and contained greyish white sebaceous-looking material, finely granular and of the consistence of thick cream. The two smallest cysts were of the size of split peas, their walls were gritty, no doubt from calcification, and their contents of orange-yellow colour and of somewhat dry and pasty consistence. On the posterior surface of the cyst and low down was a cyst similar to the small ones described but rather larger. It hung in an adhesion at a distance of ½ in. from the cyst wall. Again, loosely attached to the anterior surface of the primary cyst near the ovaries were other small cysts like those just described. They were four in number, one close

to the outer extremity of the right ovary, the other three just above the left ovary. All these with one exception had calcareous walls and ochreous contents. The exceptional cyst was larger, thin-walled, and contained clear watery fluid. It was near those of the left ovary. I believe that two small dermoid cysts like those just described were left in the abdomen at the operation and that they form the

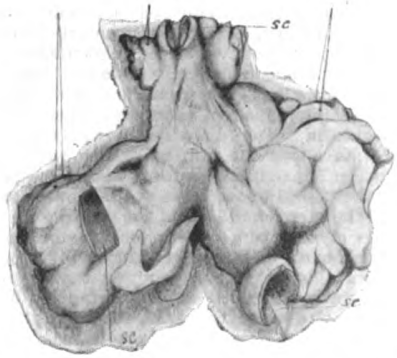


FIG. 1.

The main cyst with ovaries and tubes attached viewed from the front and left side. R O, Right ovary and tube. L O, Left ovary and tube. swellings still to be felt through the parietes. In all probability many more have been left behind, too small to be detected by palpation. Probably the correct explanation of the origin of the omental and other secondary dermoids in this case is the following: the primary dermoid and the ovary in connexion with it acquired adhesions early in its evolution. It is well known that dermoids of the ovaries are particularly liable to acquire adhesions. Subsequently other dermoids developed from the same

FIG. 2.

Portion of omentum containing five secondary cysts. S C, Secondary cysts.

ovary—that is, other Graafian follicles enlarged and became dermoidal in portions of ovarian struma adjacent to the primary cyst or in its wall. As these became prominent they became more and more intimately connected with adhesions and received a vascular supply from them and they became less and less firmly united to the primary cyst and its ovary. Finally, one at least became quite separated from the main cyst, probably by intra-abdominal movements stretching and rolling its adhesions.

Cases are recorded where a complete ovary and a dermoid in it have been detached from the broad ligament and uterus and fixed to the omentum. An early event in such cases is usually a twisting of the pedicle. The omental dermoids in my case at the time of operation were still adherent to the main cyst as the omentum itself was. They were, however, much more adherent to the omentum than to the main cyst and were therefore easily stripped from the cyst with the former. It is interesting in this connexion to notice how loosely attached to the ovaries and to one another and to the main cyst were the small cysts described above as lying on the anterior surface of the main tumour and near the ovaries. It is easily conceivable that such loosely attached cysts might be distributed within the abdomen by adhesions and abdominal movements or by complete detachment and subsequent adhesion. In 1866, before the Pathological Society of London, Mr. Chas. H. Moore of the Middlesex Hospital described a case in which many dermoids were diffused in the abdominal cavity. Many of these remained attached by long, thin pedicles to a large primary ovarian dermoid, but others were quite free among adhesions of the small intestines.

Another way in which this so-called epithelial infection of the peritoneum may be brought about is by the escape of the contents of a dermoid cyst into the cœlom—e.g., by traumatic rupture.[1] In my case there was no evidence of rupture of a cyst and for that and other reasons given above Moore's explanation of the diffusion of growths appears the more likely to be the true one. Moore wrote as follows: "Either the cysts, now separate, were once parts of the primary cyst and loosening themselves by the lengthening and then by the rupture of their pedicles they started in independent life; or, though formed in the wall of the main cyst, they were cast loose at their first extrusion from it."

The question as to whether dermoids ever arise primarily in the peritoneum independently of the ovaries is not settled by a study of cases such as these alone. It is obvious that no case in which an ovarian dermoid exists and in which peritoneal dermoids also exist can be used as evidence of the primary peritoneal origin of dermoids. It is quite conceivable, moreover, that a primary ovarian dermoid might infect the peritoneum and yet a complete and careful post-mortem examination fail to show how the infection had been brought about, though in the cases here cited there is some evidence bearing on the point. In Moore's case, for example, there were not only dermoids connected by long pedicles with the primary cyst, but in the wall of the latter there were traces of secondary cysts which had ruptured outwards. In his case both the methods of infection mentioned above appear to be illustrated. Similarly, my case appears to be an example of peritoneal infection, if the term may be used, by the extrusion of secondary cysts both with and without pedicles. Infection by the rupture of a cyst, either of the primary cyst or some secondary one, affords the best explanation of the existence of the large numbers of diffused cysts sometimes met with in these cases, though one would perhaps expect the secondary growths to have a warty rather than a cystic form. In some recorded cases they have had a warty form, with tufts of hair upon them hanging freely in the peritoneal cavity. But a transplanted epithelial mass is known to give rise sometimes to cysts in other parts, forming the so-called implantation cysts. If the peritoneal infection is the result of the extrusion of complete cysts, then the multiplicity of the secondary cysts is not explained and is very curious. It was interesting to find in a section taken from the skin patch in my specimen a considerable tract of thyroid tissue. I am much indebted to Mr. F. V. Foss, a student of the hospital, for the two drawings which are here reproduced.

Clifton, Bristol.

[1] Vide Surgical Diseases of the Ovaries and Fallopian Tubes, by Bland Sutton, Chapter x.

THE MIDDLESEX HOSPITAL.—This hospital will be closed from July 17th to Sept. 19th next for the purpose of effecting some very necessary repairs and alterations, repainting, and cleaning the whole of the hospital. No new patients will be received after July 1st, to allow of the wards being cleared by the 17th. The cancer wards, however, will not be closed and these patients will be received the same as usual.

A CASE OF REPEATED FRACTURE OF BOTH FEMORA RESULTING IN GREAT DEFORMITY.

BY DANIEL BROUGH, M.B., C.M. EDIN.,
HOUSE SURGEON TO THE DUMFRIES AND GALLOWAY ROYAL INFIRMARY.

THE following case which has come under my notice is one of interest owing to the peculiar liability which the patient displayed to fracture of the femur on slight injury and the difficulties which must have arisen in the treatment of the various fractures.

The patient was a youth, eighteen years of age, the elder son of a family of two, and had been brought up entirely in the country. The family history was good and showed no hereditary tendency towards fragilitas ossium. The father was the only other member of the family who had had a broken bone; this was a fracture of the bones of the forearm, occurring when he was a young man. The younger brother was a healthy lad working on the railway. He had never sustained any fractures and was a head taller than the patient. The patient had never been very robust and his medical adviser informed me that he had suffered from rickets and from tuberculous glands in the neck. He was 4 ft. 10½ in. in height. The first fracture occurred when the patient was ten months old. He was lying at the time on his nurse's lap and she, in stooping to raise an article from the floor, must have applied some degree of violence to the patient's leg. The medical man who was called in diagnosed a fracture of the right femur. It was treated with splints for six weeks. I have been unable to obtain any definite information regarding the site of the fracture as the medical attendant is now dead. The patient did not walk until he was twenty-two months old. At three years of age he broke his left thigh-bone for the first time. His mother was leading him by the hand and he stumbled and fell. The amount of violence to the thigh must have been slight, for he fell lightly backwards on to the floor. The bone was broken about the middle and firm union took place in a little over six weeks. Eight months after the above fracture had healed he again broke his left femur. He had been attempting to turn a key in the lock of a door. The key came away in his hand and he fell backwards. The fracture was situated at the junction of the upper and middle thirds of the femur. Union took place in nine weeks. At the age of five years, two years after the previous accident, he fell lightly on the floor and broke his left femur for the third time. The fracture was situated at the junction of the upper and middle thirds. Union took place in nine weeks. When he was nine years of age he fell backwards and again sustained a fracture of the femur on the left side at the site of the former injury. The fragments were firmly united in eight weeks. At the age of eleven years he met with another slight accident, resulting in disproportionate injury. He slipped and fell backwards on a frosty road. He was found on this occasion to have sustained a fracture of the right femur at the junction of the upper and middle thirds. In addition, the right collar bone was broken at the junction of the outer and middle thirds. The clavicle united in four weeks and the femur in eight weeks. The last accident occurred in 1897, when he was seventeen years of age. He fell forwards without much force down three steps and sustained a fracture of each femur about the middle. These united firmly in twelve weeks.

Altogether the patient had sustained nine fractures, five being in the left femur, three in the right femur, and one in the right clavicle. In the case of the left femur two of the fractures were situated in the middle of the bone and three at the junction of the upper and middle thirds. In the right femur one occurred in the middle, one at the junction of the upper and middle thirds, while the site of one, occurring in infancy, is unknown. On each occasion the accident was very slight and the resulting fractures were quite disproportionate to the nature of the fall. As will be seen from the history most of the falls were backwards. The diagnosis of each fracture was easy owing to the amount of displacement which occurred. The injuries were treated by long splint and extension and counter-extension bandages, except on the last occasion when the extension was applied by means of the pulley and weight. Owing to the large number of fractures occurring at various sites and the difficulties in the way of treatment a great deformity of the femora has resulted. How much deformity and shortening followed each fracture I am unable to say. No doubt each fracture made the succeeding one more difficult to treat. The thighs appeared to be too short for the length of the trunk and legs and a distinct projection could be seen on the outer side of each thigh even when the patient was dressed. The upper half of the left femur was markedly convex outwards. It was in a position of partial flexion and rotation outwards, the great trochanter being turned backwards. Its rounded lower end formed a marked subcutaneous projection on the antero-external surface of the thigh. The lower half met the upper half at an angle and united with it on its postero-internal aspect. The left femur was at least one and a half inches shorter than the right. On the right side the upper half of the femur was abducted

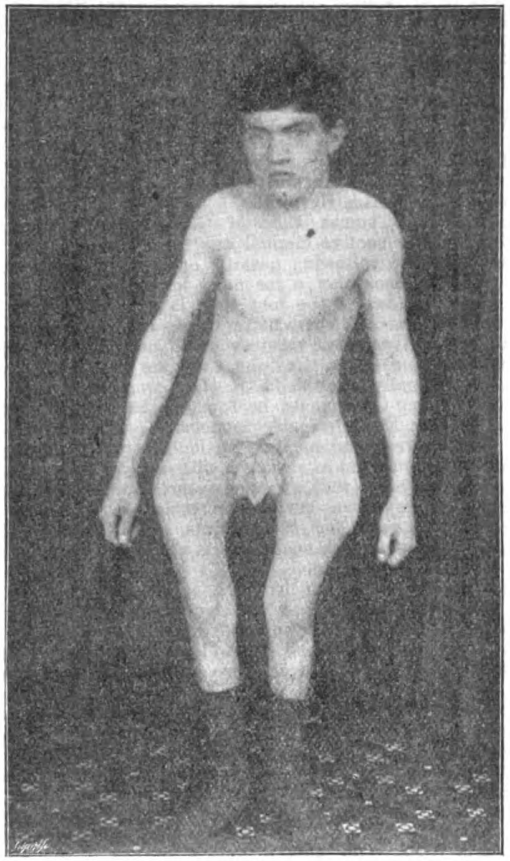

Illustration showing the grave deformity of the femora.

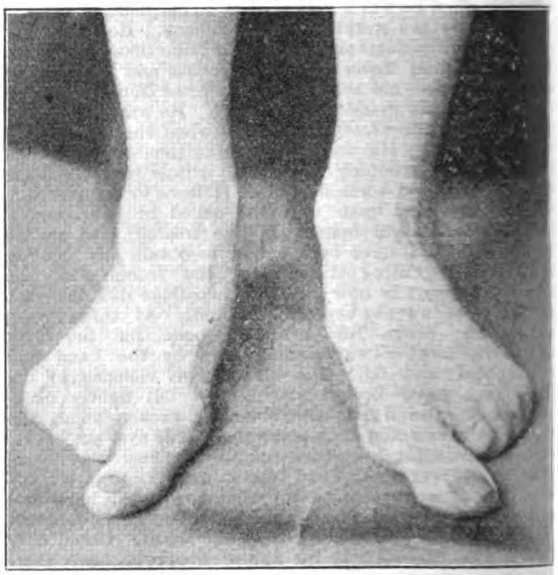
In the right femur it was the upper end of the lower half which formed the subcutaneous prominence on the outer surface of the thigh. The lower end of the upper half joined the lower half on its inner surface. There were great thickening and overlapping in both femora at the sites of the various fractures. It was difficult to estimate the amount of shortening which had taken place. It was due both to the overlapping of the ends of the fragments and to the angular deformity of the bones. Probably it was not less than six inches on the left side and it might be more. The clavicle was united in good position. The pelvis was tilted to equalise the length of the lower limbs and there was compensatory curvature of the spine. The patient was markedly pigeon-chested, the sternum being carried far forward. The other bones were normal.

I am indebted to Dr. Reid of Lochmaben for information regarding the injuries, and to Dr. Thomson of Dumfries for permission to publish the case.

Dumfries,

ON THE WALKING VALUE OF THE LESSER TOES OF THE HUMAN FOOT.



BY HEATHER BIGG, F.R.C.S. EDIN.

THE mechanical value of various parts of the human body is more surely ascertained by actual experiment than predicted by theory; hence whilst it may seem easy enough to formulate reasonable explanations of the uses of the toes it is only by their separate removal and by observing the ensuing results that a completely sound conclusion can be arrived at. In a work which I wrote in 1885 on the losses by amputation of portions of the limbs I endeavoured to show with respect to the toes that the great toe with the head of its metatarsal bone constituted the real tread of the foot and that if this tread was lost in any way it was best to discard the whole foot as useless and to remove it by Pirogoff's operation. On the other hand, I asserted that the remaining toes of the foot were mechanically of slight value and that they could be removed one and all with little detriment to the ordinary walking powers. I based these statements on my own experiences of soldiers who had lost portions of their feet from frost-bites or otherwise during the Crimean campaign and whom I afterwards saw as pensioners of Chelsea Hospital.

In 1889 Mr. Thomas Ellis of Gloucester published an erudite and instructive manual on "The Human Foot" in which work the following passage occurs: "Here let it be said that the toes play a far more important part in the ordinary functions of the foot than is generally admitted. One sees statements (where better things might be expected) to the effect that their services could be dispensed with. Even in walking, as usually done, they are used much more than is generally supposed. If they were not used the muscles moving them would be found to be wasted." Now as I read Mr. Ellis's valuable monograph with considerable care and interest, and as this particular opinion expressed by him was somewhat at variance with my own experience, I was in the hope that at some future time a case might arise under my own entire observation which could be appealed to as settling these points of difference, and I think the following instance, from its absolute completeness, may be cited as doing so.

The patient was born in 1871. Her history prior to my seeing her was, in her own words, as follows: "At the age of two years I suffered with terrible chilblains, which were so neglected that it was only with the greatest care that the toes were saved. Since then my toes have always troubled me. The two little ones began to contract when I was ten years old, and this contraction caused corns which by the time I was fifteen were so bad that they suppurated. I was then under a chiropodist of Manchester, who used to relieve them, but only for a time. Finally, when they pained beyond all endurance, I went to a consulting surgeon in Liverpool, who suggested their tendons being cut, and this was done by our own doctor in April, 1892. As this operation proved of no effect in relieving the continuous and excruciating pain, he amputated both the little toes in June of the same year and with immediate relief. The other toes at this time were not much affected, but by March, 1893, they also had become contracted, causing me much pain, and finally severe corns similar to those formerly on the little toes. In January, 1894, I consulted Mr. Barnard Holt of Savile-row, who recommended complete stretching of the tendons under chloroform and subsequent mechanical extension." Such was the patient's own account of herself. When I first saw her with Mr. Barnard Holt she was a fine, well-proportioned girl, with no other trouble with regard to her health than that due to the persistent pain in the toes. With respect to these toes the contraction of the extensor tendons was by no means spastic, but appeared to be rather accommodative and due to an instinctive effort to save them from coming to the ground in walking. The toes themselves were enlarged and bulbous, their surfaces being covered with corny, unhealthy skin. Further, they were not only painful whilst in boots, but were also so at night and to such an extent as to frequently prevent sleeping.

On Feb. 6th (the extension apparatus having been in the interim prepared) the patient was anæsthetised and the toes were fully and forcibly overflexed on to the plantar aspect of the foot. This was readily done without material resistance.[1] During the six ensuing months mechanical extension on the original plan was pursued, but it soon became evident from the exquisite tenderness of the toes that this method, which answers well enough in simple cases, could only here be intermittent and unsuccessful. Seeing therefore no other alternative and feeling confident that the issue would be satisfactory I advocated amputation of all the remaining lesser toes of both feet and, having obtained the sanction of the patient's father, I took her to Mr. Augustus Pepper for his opinion as to the advantages of the operation. Mr. Pepper's judgment being also in its favour he, on Nov. 10th, removed all the remaining lesser toes by separate incisions, kept well on the dorsal aspect of the foot so as to avoid any chance of the cicatrices being involved in the subsequent tread. The wounds all healed by first intention and within three weeks the patient could stand on her feet which presented the appearance shown in the accompanying illustration reproduced from a photograph which I took

of them. The subsequent results have been such as to justify the wisdom of the operation and to prove distinctively that the lesser toes are not of the paramount value sometimes assigned to them. As the patient lived at a distance and as there was no necessity to keep her in town for observation I asked her to periodically write to me reports of her progress and of this the dated extracts from her letters will probably form the best record.

Dec. 30th, 1894: "I am able to walk perfectly on my feet with little or no pain, but cannot yet wear either slippers or boots as they are still tender."—Jan. 15th, 1895: "I managed to get on my slippers yesterday and wore them with ease for more than six hours."—Jan. 28th: "I put on my boots to-day for the first time. It still pains me slightly to walk, otherwise my feet are going on all right."—Feb. 18th: "I ought to say that the steel plates only half way answer splendidly."—March 24th: "You will be glad to hear that I can walk splendidly now, just like a proper human being; it is just eighteen weeks next Tuesday since the operation."—May 5th: "I have decided to come to town next Monday week to let you see how well I can walk."—June 17th: "I played two sets of tennis on Saturday, and my feet were none the worse afterwards."—July 24th: "You will be surprised to hear that the big toes have lengthened ½ in. since the operation, and I have had all my boots lengthened and the toe line made straighter."—Aug. 30th: "I know that you will be interested to hear that I have just accepted an invitation to

[1] It is a melancholy accompaniment to this case that the late Mr. Barnard Holt became in the middle of this slight manipulation suddenly indisposed and the same day he took to his room which he unhappily never left again. The case, therefore, accidentally passed entirely into my hands.

a dance on Sept. 13th. Whether I shall dance comfortably or not is another thing."—Sept. 14th: "I went to the dance on Tuesday evening and thoroughly enjoyed myself after not dancing for so long. My feet were on their best behaviour, and did not pain me once during the evening. I never realised before that I had no toes until I began to dance, then it seemed so odd only to have one toe, but I suffered no inconvenience whatever from the loss of them."—Dec. 5th: "I get on so well with my bicycle."

It is unnecessary to carry these extracts further: suffice it to say that the patient has been able to walk, cycle, dance, play tennis, and to pursue, in short, every other exercise and amusement which girls of her own age enjoy.

As regards the mechanical assistance which it seemed advisable to give to the tread of the foot during the healing process it may be stated that with her first boots she had a thin steel plate extending the whole length of the foot and lying between the leathers of the sole. After three months these plates were reduced so as to only extend from the instep forwards and before the end of the year it was found that the narrow steel spring beneath the great toe was all that was requisite. These adjuncts to the sole were used to assist the great toe in acquiring complete usage to the tread of the foot. Further, to prevent the foot spreading transversely whilst the tissues at the heads of the metatarsals were consolidating a strip of Leslie's plaster an inch broad was for some time worn round the foot.

Only two disadvantages showed themselves as the result of the operation and these were temporary. One was that the great toes tended to pervert themselves towards the middle line of the feet, a thing which was readily remedied by the use of single-toed stockings and by packing the space in the boot left vacant by the missing toes with cotton wool; the other was a loss of local sense on the outer sides of the feet, which went to show that the lesser toes were missed rather as tactile organs than anything else. This failure of feeling righted itself in time presumably by a vicarious and intenser sense being acquired by the skin of the outer side of the foot. In all other respects the loss of the toes discovered no inconvenience.

There is only this to be added, that whilst the feasibility of so complete an operation is demonstrated in this particular case it would be needless to resort to it except in rare instances. Ordinarily contracted toes can be dealt with by much less radical measures if the toes themselves be sound. Still there are frequent instances in which even after mechanical extension or division of the tendons the toes revert into their inconvenient position and in such cases amputation can be adopted without scruple. I recall an instance of a gentleman whose family had an apparently hereditary disposition to contraction of the third toe in each foot. I took him to the late Mr. Berkeley Hill, who divided the extensor tendons and the toes were readily straightened, but after some time they recontracted; finally, they were amputated without the slightest detriment to his powers of walking and the inconvenience was once and for all removed. This, of course, was only one toe in each foot, but there appears no reason why in necessary cases all or any of the lesser toes should not be removed without crippling disadvantages. I believe that the excellent results in the complete case I have here recorded are largely due to the method Mr. Augustus Pepper adopted of keeping the cicatrices clear of the ultimate tread of the feet.

Wimpole-street, W.

AMYLOLYTIC FERMENTS.

BY WYATT WINGRAVE, M.R.C.S. ENG.,
ASSISTANT SURGEON TO THE CENTRAL LONDON THROAT AND EAR HOSPITAL.

THE personal necessity for a starch ferment having suggested a few experiments with several easily obtainable preparations, the experience so gained may possibly prove helpful to others in their selection of a ferment from a group which clinically receives less attention than the proteolytic does.

Choice of ferment.—Starch ferments may be divided into two chief kinds, according to their sources: (*a*) animal, prepared from glands—ptyalin (salivary), amylopsin (pancreas); and (*b*) vegetable or diastatic. The preparation of group *a* is not only attended with some technical difficulty but the products are too unstable and unreliable to become generally available. Not so those of the second group. These, for the most part, are easily obtained, stable, reliable in action and economical in price. The best-known examples are malt-diastase and taka-diastase. Malt-diastase occurs in markedly varying proportions in all extracts of malt (moist and dry), while taka-diastase is prepared by making a cultivation of Eurotium oryzæ (of the Aspergillus group) on hydrolysed wheat bran. The diastatic influence is extracted with water and separated by evaporation as a scaly powder which is readily soluble in water and possesses well-marked hydrolytic power. Many samples were tested against normal saliva and the following three examples were eventually selected as fair representatives of the second group: (1) Kepler's malt extract (moist); (2) Wilcox's desiccated malt extract (dry); and (3) taka-diastase (dry). These were tested chemically and clinically.

Chemical tests.—It must be borne in mind that the condition of all test-tube experiments must differ considerably from normal and morbid digestive changes, and, however carefully carried out, the results must only be judged as approximate. The first series of trials were made in order to ascertain which of the preparations possessed the greatest amount of diastatic power. It would be tedious to detail them all, but the following are illustrative and can be done by anyone. First experiment (test-tube): 20 gr. of malt extract (moist), 5 gr. of malt extract (dry), and 1 gr. of taka-diastase were mixed respectively with 100 minims of a 5 per cent. solution of arrowroot, neutralised and placed in a water bath at 38° C. At the end of twenty minutes the malt extract gave erythrodextrin and a trace of maltose; the taka-diastase chiefly maltose and soluble starch and the desiccated malt chiefly soluble starch. (Saliva gave soluble starch in excess with trace of maltose.) Second experiment: A thick paste consisting of 3 oz. of arrowroot (representing a full meal of carbo-hydrates) boiled with 15 oz. of water, cooled to 40° C. and rendered faintly alkaline, was placed in a flask with 300 grains of Kepler's malt extract, 150 grains of desiccated malt, and 15 grains of taka-diastase respectively. The flasks were placed in a water bath, kept at a temperature of 38° C., and shaken every three minutes. At the end of five minutes the Kepler's malt extract and desiccated malt showed no change, while the taka-diastase could readily be shaken, the paste being broken up and about one-third appeared fluid. In ten minutes it was only lumpy in the centre and in thirty minutes the lumps had quite disappeared, while the Kepler's malt extract and desiccated malt were nearly as gelatinous as at first. It was found that the products of the taka-diastase action were soluble starch, maltose, and erythrodextrin, the original arrowroot being entirely changed while the Kepler's malt extract and desiccated malt only afforded small quantities of sugar, soluble starch and dextrin. This test indicates that taka-diastase possesses greater hydrolytic power than either of the malt extracts, which may be due either to a higher ferment potential or to a greater range of action under disadvantageous and artificial conditions, such as accumulation of sugar and intermediate products, &c. It was further observed that increase of the temperature up to 50° C. increased the action of the malt extract.

Having considered the behaviour of these ferments under what might be termed favourable conditions the next point was to watch them under morbid influences similar to those occurring in so-called dyspeptics. During pyrosis, lactic acetic and butyric acids are present in proportions variable yet minute. A sufficiency of each acid was added to starch solutions to produce the well-known acid taste and the solutions were then watched under the same conditions of temperature as in the other tests. In each case the starch was converted after three times the duration of the exposure used in the other tests into soluble starch and slightly to erythrodextrin, but sugar only appeared in very small quantities after three to four hours. The addition of neutral peptones and proteids did not appear to exert any influence. The presence of 0·2 per cent. of hydrochloric acid after exposure for twenty minutes permanently killed all the ferments, but for a less period activity was restored on neutralisation. Quinine dissolved in citric acid did not inhibit unless the strength exceeded 0·5 per cent., a point which is of clinical interest since my experience has shown that small doses of ½ gr. to 1 gr. undoubtedly act beneficially in cases of pyrosis. The ferments were then tested with raw starch as represented

by scraped fresh potatoes, upon which, like saliva, they had no hydrolytic influence whatever.

Clinical tests.—Having seen that butyric, acetic, and lactic acids retarded the conversion of starch into sugar, their neutralisation was obviously necessarily essential to a satisfactory ferment action in cases of pyrosis. A preliminary preparation of the stomach by means of small doses of carbonate of magnesia and chalk in the form of lozenges, or sodium carbonate dissolved in chloroform-water, proved effectual. For it must be borne in mind that, normally, starch conversion is carried on in the stomach, not in the mouth, and it has every opportunity of being completed in the stomach, since hydrochloric acid may not appear free for from half to one hour. But it is extremely doubtful what proportion of work the stomach and intestines respectively perform in a person living at high tension with an irritable digestive tract. As hydrochloric acid is necessary for exciting and maintaining proteolysis so alkalies are essential for proper starch conversion, and it is almost useless to attempt the digestion of starch in cases of pyrosis without their aid. It is probable that in a very high percentage of cases described as dyspeptic the starch conversion is mainly at fault, and consequently the case shows no improvement under pepsin treatment.

Clinical observations supported the test-tube evidence. The dry malt extract not only acted as a powerful sialogogue, being a pleasant substitute for jam when eaten with bread-and-butter, but the after-effect undoubtedly gave evidence of a greater diastatic power than the artificial tests led one to expect. The fluid malt extract seemed to increase the pyrosis to such an extent that it had to be discontinued in several cases, while in others the excessive sweetness was tolerated and its diastatic action seemed satisfactory. Still the excess of sugar and its bulk more than counterbalanced its diastatic value. Taka-diastase, on the other hand, being free from sugar, is entirely without these disadvantages and its action is unhampered.

The conclusions may thus be briefly summarised: 1. That of the commercial starch or diastatic ferments taka-diastase is apparently the most powerful and the most reliable since it is more rapid in its action—i.e., it will convert a larger amount in a given time than will any other amylolytic ferment. 2. That organic acids, such as butyric, acetic, and lactic, the acids most frequently present in pyrosis, &c., do retard but do not permanently kill the ferments, and when neutralised are harmless. That taka-diastase seems to be less influenced by them, and also by tea, coffee, and alcohol, than are saliva and malt extracts. 3 That hydrochloric and other mineral acids quickly stop and permanently destroy all the starch ferments if allowed sufficient time and if present in sufficient quantities. 4. That taka-diastase and malt diastase have, like ptyalin, no action upon cellulose (uncooked starch).

Devonshire-street, W.

NOTE ON A CASE OF ANGULAR CURVATURE OF THE SPINE IN AN ADULT.

BY CHISHOLM WILLIAMS, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.,
ASSISTANT SURGEON, CITY ORTHOPÆDIC HOSPITAL, E.C.

THE patient was a man, aged fifty-six years. His family history was good. His parents are living. The patient is an only son. He had had measles and scarlet fever in early childhood. There was no specific history. Early in the year 1888 on returning from America he was thrown somewhat violently from the upper of two sleeping-bunks to the floor and "wricked his back," which remained painful for a couple of weeks. He then visited the south of France for some months and felt fairly well during this time. During the winter of 1888–89, he noticed that the pain in his back (the dorso-lumbar region) was of a gnawing, dull character with a general feeling of "weak back" which was increased on stooping or hurrying about but was relieved during the night in bed and in a less degree when lounging in an arm-chair. He also noticed feelings of cramp in the calves but of a very slight character. In 1890–91–92 the back symptoms remained fairly stationary but he had two attacks of influenza, laying up for two and three weeks respectively. At the end of 1892, the symptoms becoming greatly aggravated, he was advised to see one of our leading neurologists, who treated him for some months with drugs, diet, &c., and the back was "fired" on seven occasions and the resulting marks bear evidence of the thoroughness of this part of the treatment. In 1893 the pain was almost continuous, being still dull and gnawing, and at times he had attacks of severe cramps, mostly at night. His gait became unsteady, he not being able to walk in a straight line. He was also noticed to stoop very much. Towards the close of the year intercostal neuralgia, chiefly of the right side, much abdominal pain, and other vague sensations about both the abdomen and the limbs made themselves manifest. For the relief of these pains his medical attendant had repeatedly to inject morphia and to give opiates at night. In January, 1894, he was first seen by me, and he then presented the following condition. He complained of two kinds of pain: one a dull, gnawing, incessant pain, slightly mitigated by the use of morphia, situated on either side of the spinous processes of the tenth, eleventh, and twelfth dorsal and first lumbar vertebræ, extending 3½ in. to the right and about 1½ in. to the left; the other a radiating neuralgic pain which darted round the intercostal spaces and down the lower limbs. A peculiar sensation he described was a cold creeping from the sacrum up the spine to the nape of the neck. At this time he had also early-morning cramps of the side and back muscles.

On examination his general appearance was that of a man who had been for a long time a chronic sufferer. He was extremely emaciated, weighing barely 8 st., and being 5 ft. 9 in. in height. His walk was an elongated zig-zag; he also walked somewhat sideways, with the right shoulder in front and slightly higher than the left one; the back was always held perfectly rigid; the spine presented a well-marked slightly reddened "boss" from the tenth dorsal vertebra to just below the first lumbar vertebra on the left side; on a level with this boss was an induration and a sense of resistance over an area of the size of an adult palm. On the right side there was a distinct bulging which was raised about ½ in. above the surrounding skin. At this part deep fluctuation could be easily obtained outwards for a distance of 2½ in. but no further, nothing could be detected in front or towards Poupart's ligament. Over the three lowest intercostals, the right side, and the right half of the abdomen to just below the anterior superior spine of the ilium a condition of hyperæsthesia was observed and several patches at the upper part of the right thigh (back and front) and at the back of the right calf. The rest of the leg seemed anæsthetic. The temperature varied from 99° F. in the morning to 100 5° at night.

Treatment.—The patient objected most strongly to any form of treatment which would confine him to the house, much less to his room, so all thoughts of the prone position had to be abandoned. He stayed in bed, however, for a week whilst the fluctuating swelling was aspirated and nearly 3 oz. of thick yellow pus were removed. Towards the end of the week it was again tapped of about 1 oz. of thin serous fluid, slightly blood-stained. By this time a simple metal spinal support was procured, after the pattern of the late Mr. E. J. Chance's, and was accurately adjusted; the most severe part of the pain ceased in a couple of weeks. By the end of six weeks the cramps and hyperæsthesia had also vanished. The morphia was discontinued after the first week. A course of strengthening and tonic treatment was then carried out, cod-liver oil, syrup of hypophosphites, and malt extract being the chief aids, and was kept up fairly well for a couple of years. The splint was worn day and night for twelve months only and then it was left off unknown to his medical attendant or to myself. When I next saw him, about eighteen months after putting the splint on, he had left it off six months and felt quite well, every symptom having disappeared. The "boss" remains the same, but by being able to hold himself more upright his appearance is greatly improved.

The case is interesting on account of the shortness of the period of treatment in an adult. It consisted of only one week in bed, one year of mechanical support, and two years of intermittent medical treatment. I have seen the patient again this year (1898) and he says he is quite well, having had absolutely no trouble with his back for the past three years or so.

Bishopsgate-without, E.C.

ON SOME MENTAL FACTORS IN THE CAUSATION OF DEATH UNDER CHLOROFORM.

BY ROBERT BALLARD, M.R.C.S. ENG., L.R.C.P. LOND.

THE chloroform controversy has not yet ceased to interest the profession as a whole, and at this stage it may not be inopportune to draw attention to certain clinical aspects of the question which, in the purely academical phase which the discussion has now assumed, are in danger of being overlooked or forgotten. The published conclusions of the Hyderabad Commission have given the much needed stimulus to a closer investigation of the facts connected with the mechanism of death under chloroform. The storm of criticism which those conclusions evoked has resulted in the valuable physiological inquiries of Dr. Leonard Hill and others, and the interest which has been aroused by their investigations into what may be called the hydrostatics of the circulation is apt to divert attention from the significancy of the fact that all laboratory experiments are necessarily conducted upon animals and to cause us to forget for a time the personal equation which enters so largely into all questions connected with the human organism.

In 1894 I recorded in the pages of THE LANCET[1] a case of cardiac syncope under chloroform — happily ending in recovery—in which the predisposing cause of the accident was undoubtedly the terror and mental anxiety of a nervous lad subjected for the first time to an experience the dangers of which were to him the more alarming because unknown. The horror with which some persons regard the idea of an anæsthetic is to many people incomprehensible, but it is none the less real, and I am convinced that the importance to the administrator of ascertaining the mental attitude with which the patient approaches the operation cannot be overestimated. In some cases operative measures are decided upon and the patient's consent obtained three or four days before the operation is finally performed, and during the intervening sleepless nights and long weary hours of waiting in bed the ever-present idea of operation looms larger and larger in the patient's mind. With sickening reiteration he dwells again and again upon what he may imagine to be the details of the operation and endures in anticipation a mental agony out of all proportion to the actual facts. Is it rash to assert that such a patient will be brought to the table with nervous and circulatory systems heavily handicapped for the strain which will be put upon them?

The following case which occurred in my own practice well illustrates the grave condition which may be produced by fear and anxiety. A woman, aged twenty-three years, single, had suffered from frequently recurring attacks of appendicitis of considerable severity and it was decided during a period of quiescence to perform laparotomy for the removal of the diseased appendix. The patient was a pale, nervous woman, much reduced in health by her former attacks, and with a marked neurotic family history on the mother's side. I first saw her the morning before the operation. She was then evidently anxious, but evinced, as far as I could judge, no signs of great mental distress. The pulse was 98, dropping ten minutes later to 89. The heart was normal in every respect and the sounds, though hurried, were clear. On asking her to sit up I fancied I could detect a faint hæmic murmur at the pulmonary base. An examination of the chest gave negative results. When I left the pulse was 84, having dropped 14 in less than half an hour. I did not see her again until the following day when she was brought into the next room for operation. Her condition was then typical. The heightened colour, hurried irregular respiration, compressed lips and fluttering eyelids spoke of the fear and suppressed excitement from which she was suffering. The pulse was 104, and the heaving impulse of the heart could not only be felt but seen. The superficial veins of the neck were slightly engorged, and on careful scrutiny showed a faint but distinct pulsation. Indeed, her condition was so serious and the engorgement of the right side of the heart so obvious that I was in doubt as to whether it was justifiable to operate at all. At the last moment I decided to give gas and ether, in spite of a slight bronchial catarrh from which the patient had been suffering. The sight of the Clover's inhaler added the last straw to her terror, and when on the table she begged that the operation might proceed without an anæsthetic. When fully under the influence of nitrous oxide the signs of engorgement disappeared, the pulse-rate fell, and she eventually took the ether well and made a good recovery.

The chief element of danger in these cases is the profound disturbance of the circulation which commences in many cases some days previously and persists until the patient is well under the influence of an anæsthetic. In the worst cases there are signs of serious embarrassment of the right side of the heart and in two cases I have observed an undoubted temporary tricuspid regurgitation—physiological, no doubt, but none the less dangerous. It may be urged that inasmuch as this condition passes away as consciousness is lost its gravity has been exaggerated; but it is when the patient is still conscious and is struggling and holding his breath that the greatest stress is laid upon the heart and the occurrence of sudden syncope is most to be feared. Every anæsthetist knows that children bear chloroform, on the whole, better than adults and that the victims of sudden accidents necessitating operation are not so liable to syncope as the serious shock they have sustained would lead one to expect. Children, in fact, are in much the same position as Surgeon-Lieutenant-Colonel Lawrie's dogs: they are spared the depressing effects of anticipation and their fear does not begin until they are actually on the table and is then of short duration; and the victims of severe accidents are so overcome by the suddenness of the shock and by the maiming or mutilation which may result that the administration of an anæsthetic is looked upon as a detail of minor importance and an operation of some kind regarded as a matter of course. National character, also, may have more to do with the absence of fatalities from chloroform obtaining in Edinburgh than from any peculiarity in the exhibition of the drug.

In the majority of private operations the anæsthetist is a stranger to the patient. This, when possible, should be remedied. Every surgeon must have remarked the good effect produced upon a nervous patient by a cheerful and optimistic view of the approaching operation when expressed by a comparative stranger and one entitled to speak with authority. Where there are signs of great anxiety and engorgement of the right heart I prefer to give gas and ether. But occasionally these cannot be obtained or are distinctly contra-indicated and chloroform has to be used. It is here that morphia is so useful. One-sixth to a quarter of a grain should be injected at least half an hour before the administration with, as a rule, the happiest results. Where morphia again is contra-indicated—and in spite of the text-books such cases are rare—one would naturally turn to the bromides of ammonium and sodium, but I have not yet had occasion to use these drugs.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF FRACTURED RIBS FOLLOWED BY TUBERCULOUS CASEOUS PNEUMONIA AND DEATH.

BY ROBERT E. LORD, M.D., B.SC. LOND.

THE case of pneumonia following injury and leading to fatal tuberculous mischief in the lung recorded by Dr. Thomas Harris in THE LANCET of April 16th, 1898, induces me to report the following case, which is the only one of the kind I have seen during five years' practice in a health resort to which cases of phthisis are constantly sent during the winter.

A man, aged twenty-nine years, was seen by me in December, 1894, and gave the following history. Until the previous September he had enjoyed good but not robust health. He had not suffered from any but the illnesses of childhood and had always been of strictly temperate habits. He had led a sedentary life, taking very

little exercise and spending his days in his office and his evenings at home or in places of amusement. His family history was good except in the case of his father, who had had a cough accompanied by much expectoration and loss of flesh for some months before his death which happened in the spring of 1894 from pneumonia. In September the patient while at his office was "larking" with some fellow-clerks and fell against the corner of a table, striking the upper part of the right side of his chest against it. He felt severe pain which was so violent as to compel him to go home, where he was seen by his usual medical attendant, who found fracture of three or four upper ribs and applied strapping and sent him to bed. During the evening a small quantity of bright-red frothy blood was expectorated. On the following day he was feverish, the pain still continued and there were signs of pleurisy. Slight hæmoptysis occurred for some days, and signs of consolidation were developed, and later of softening at the right apex. The temperature for several weeks reached from 101° to 102° F. in the evening; he lost flesh, had severe night-sweats, and about a month after the receipt of the injury had a severe attack of hæmoptysis, after which he temporarily improved and was able to be moved to Colwyn Bay in October. In December, when I first saw the patient, he had signs of an extensive cavity in the right apex and of consolidation with some softening at the left. There were large masses of hard lymphatic glands in both supra-clavicular fossæ, especially on the right side, and on this side they were said to have developed soon after the accident. The evening temperature varied from 101° to 103°, falling to 99° or thereabouts in the morning. He had severe night-sweats, much cough, and profuse expectoration containing many tubercle bacilli. The disease rapidly spread to other portions of the lungs; the larynx and pharynx became affected and ulcerated very extensively, and he died on March 31st, 1895, about six months after the accident which apparently originated the affection.

Remarks.—There was evidently a lesion of the lung caused by the fractured ribs either at the time of the accident or within a few hours of it and a favourable site for the growth of tubercle bacilli was thus prepared. From the facts that he had led an in-door life, that he had lived for years in the house where his father (who probably had phthisis) had lived and died, and that the signs of tuberculous infection showed themselves very soon after his fall, it seems fair to assume that he probably already had in his respiratory tract tubercle bacilli which were only enabled to flourish when the special opportunity thus offered arose. This they seem to have done most luxuriantly, as his symptoms were of the acutest character from the very first. It appears that either the infection must have been a very severe one or the powers of resistance of the patient were very slight. No necropsy was obtained, and therefore no opinion can be hazarded as to whether or not he had any tuberculous lesions of older date than the accident.

Colwyn Bay.

TWO CASES OF PERFORATION OF THE INTESTINE BY ASCARIDES.

BY P. APOSTOLIDES, M.D.,
PHYSICIAN TO THE GREEK ROYAL NAVY.

IT is known that round worms can enter the various ducts and organs communicating with the digestive tube in their normal condition, but perforation of the sound intestine by ascarides is a very rare occurrence. The event has been much discussed and even doubted by many authors. According to Davaine, Niemeyer, and others the perforation could only take place in the event of the mucous membrane having been previously ulcerated. Other authors have either discussed the fact or leave it unmentioned. However Leuckart, Mandière, and Magnac say that ascarides can penetrate the peritoneum by primitive perforation of the sound mucous membrane. Charsley also reported some time ago an observation in favour of this assertion. This accident is in my opinion much more frequent than is commonly supposed. I am led to this conclusion by the observation of two such cases in the space of ten years at the Naval Hospitals of Piræus and Salamis. One of these two cases I have already published in the medical journals Ταγγρός of October, 1886, and *La Semaine Médicale* of Nov. 27th, 1886. The second case I now send to THE LANCET, repeating also the first.

The patient in the first case was a man who was admitted to the Naval Hospital of Piræus with attacks of simple intermittent fever. On the night of the fourth day after his admission he presented all the symptoms of intestinal perforation and acute peritonitis and died in the evening of the following day apparently from that cause. At the necropsy the cavity of the peritoneum was found to be full of a sero-purulent fœtid liquid. A little above and to the right of the umbilicus the head of a live ascaris was detected. Upon careful examination, between the jejunum and ileum, in a portion of the intestine otherwise perfectly sound, there was found a small, circular perforation of the size of a lentil, through which the ascaris had penetrated into the cavity of the peritoneum. In the intestines there were also numerous ascarides but the mucous membrane was perfectly sound in all its extent.

The patient in the second case was a sailor, aged twenty-two years, who was admitted into the naval hospital of Salamis on May 7th, 1897, with violent pains in the abdomen, meteorism, foul tongue, and a temperature of 39·2° C. (102·6° F.). During the four days that he was under observation he showed symptoms of peritonitis which would not yield to any treatment and he died on May 11th. At the necropsy the peritoneum was found full of a sero-purulent liquid. At the upper part of the ascending colon there was discovered a perforation of the size of a lentil and from it was removed part of an ascaris the remaining portion of which was found inside the intestine.

As these two cases came under my notice in so short a space of time it is probable that many similar ones occur without their true nature being recognised and that the symptoms are wrongly attributed to peritonitis of tuberculous or other nature.

Piræus, Athens.

A CASE OF DEAD TWIN RETAINED TO FULL TIME.

BY DAVID ROSS, M.B. ABERD.

ON Feb. 15th, 1898, I was called by a Royal Maternity Charity midwife to see a woman, aged thirty-two years, a poor Jewess, whom she had just delivered. The patient was the mother of five healthy children, two of them being twins. During the first three months of her pregnancy she stated that she thought she was carrying twins, the early symptoms being very similar to those of the previous occasion on which she had twins. One morning in her fifth month, after she had felt quickening, she stated that she had had a fright, and on that evening severe metrorrhagia set in which lasted for three days; then for three months after she had a slight yellowish discharge. During the last four months she said that she distinctly felt the movements of a child on the right side, but that in the lower part of the abdomen on the left side she felt as if she were carrying a stone and had a feeling of great weight and dragging pain. Labour began on Feb. 13th at midnight and continued all next day till 6 P.M., when she was delivered, with little trouble, of a dead fœtus about five months old. The midwife waited, as she knew there was another child, and at 8 A.M. on Feb. 15th she was delivered, after a very severe labour, of a fine, healthy, full-time girl. The body of the fœtus was flattened antero-posteriorly, while the head, due to a twist on the neck, was flattened from side to side. The skin was soft, moist, and tough, was very pale, and felt like wet chamois leather; but there was no offensive smell or any sign of decomposition. The features were quite unrecognisable and the sex was indistinct.

The interest attaching to this case is that in spite of the excessive metrorrhagia at the fifth month the dead fœtus was retained, constituting rather an uncommon case of missed abortion.

Kingsland-road, N.E.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.—The annual report of this institution states that 1273 in-patients were admitted during 1897, being 62 in excess of the previous year, and 2445 out-patients were treated, against 2660 in 1896; 259 patients were sent to the Pearn Convalescent Home. The ordinary income for the year was £5762 and the total expenditure was £6129.

KING'S COLLEGE HOSPITAL.

A CASE OF TUBERCULOUS ABSCESS IN THE ABDOMEN COMMUNICATING WITH THE RECTUM; OPERATION; RECOVERY.

(Under the care of Mr. WATSON CHEYNE.)

On Dec. 8th, 1893, Mr. Watson Cheyne was asked by Dr. Lendon to see a patient, aged twenty-six years, who had been knocked down by a runaway horse two years before while she was carrying a pair of skates. She fell on the skates and hurt her right side in the inguinal region. About four months afterwards she noticed a swelling on the right side towards the middle line at the lower part, but she did not consult anyone till the autumn. She was then found to have a swelling towards the inner part of the right iliac fossa and extending in the direction of the middle line; the swelling was fairly large and fluctuating. At that time she saw a gynæcologist who sent her to an ovariotomist for operation, but neither of these gentlemen seems to have made a definite diagnosis. In October, 1892, an incision was made above the pubes in the middle line and a little pus was found in the lower part of the abdomen; nothing further was done except that a drainage-tube was inserted. This was kept in for about ten weeks and when it was left out a sinus remained which had never healed. The discharge was at first comparatively slight but steadily increased. The patient went to the seaside and to the country and tried in various ways to improve her general condition. Not very long after the operation it was noticed that pus was being passed per rectum and of late the quantity of pus so passed had increased very considerably. She had also of late been going down hill very rapidly; she was markedly emaciated, had profuse night sweats and hectic temperature, and the pulse varied from 120 to 130. A large quantity of albumin was present in the urine. She had lately seen the gentlemen who operated on her before, but they declined to do anything further and it became quite evident that she was losing strength rapidly.

On examination the patient complained of a great deal of pain on the right side of the abdomen at the lower part, especially on pressure. She was very much emaciated, had night sweats and hectic temperature in the evening ranging between 102° and 103° F., and there was about one-eighth of albumin in the urine. On examination a sinus was seen in the middle line about 1 in. above the pubes, and a probe passed into this sinus went backwards and somewhat to the right for a long distance—in fact, the whole length of a small probe passed in. With the finger in the rectum a thickening was felt as high up as the finger could reach and a mass was also felt in Douglas's pouch, and when the finger was withdrawn it was found to be covered with pus. On vaginal examination a large mass was felt lying towards the right side, slightly moveable but attached to the uterus, which was pushed towards the left. The probe passed into this mass, running down along the right side of the bladder. Bimanually the mass could be very distinctly felt and seemed to fill up the whole region from the rectum to the situation of the sinus in front and towards the right side.

As it was evident that the patient was going down-hill very rapidly Mr. Watson Cheyne determined to explore the sinus more thoroughly and see what could be done with the view of remedying the disease and if possible shutting off the communication with the rectum. Accordingly on Jan. 3rd, 1894, the bowel having been well cleared out and the patient having been placed under the influence of an anæsthetic, a long probe was inserted into the sinus and the opening was sufficiently enlarged in a downward direction to admit the finger, great care being taken of course not to injure the bladder. On gradually dilating the sinus and inserting the finger it passed into the centre of broken-down material and portions of this on being taken out looked like masses of granulation tissue, but it was not certain that they were not masses of tumour substance. It seemed upon consideration that the only chance which the patient had was to attempt to excise the whole mass, even although one ran a great risk of setting up a suppurative peritonitis. Hence the incision was enlarged upwards to the extent of five or six inches, the abdomen was opened, and the intestines were pushed upwards to the left and were guarded with flat sponges. On examination with the hand in the abdomen the mass was found to be adherent to the bladder on the right side and to the right side of the uterus, the ovary and Fallopian tube on that side not being distinguishable from it, and it extended backwards into Douglas's pouch and was adherent to the rectum behind. Having ascertained the connexions of the tumour with the hand in the abdomen it was gradually peeled off from the various structures, beginning at the bladder in front. The front of the mass was gradually detached without any very great difficulty and then it was found that the broad ligament and ovary were firmly embedded in it and the ligament was therefore tied in two places and divided. The mass was then peeled off from the uterus, from Douglas's pouch, and from the rectum, and ultimately was removed as one mass. There were only a few adhesions to the intestines. There was no troublesome bleeding. When the mass had been removed it was found that there was a large hole in the rectum which almost admitted the little finger and a probe could be readily passed through it and out at the anus. The condition left was therefore a raw wound in the pelvic cavity with the uterus, bladder, and rectum forming part of the wall of it, an opening in front, free communication with the rectum, and free communication with the peritoneal cavity. Owing to the great depth of the parts no attempt was made to stitch up the hole in the rectum. The pelvis having been sponged out five large drainage-tubes were inserted, these extending right down to the hole in the rectum, and the rest of the wound was then stitched up and an antiseptic dressing was applied. The patient stood the operation extremely well and was not collapsed afterwards, nor was there any vomiting.

On the following day (Jan. 4th) the temperature rose in the evening to 99·2°, having been in the morning only 88·6°. The pulse was full and 100. The patient was very well, taking her food well. The wound was dressed twice; there was no odour about the dressing; the drainage-tubes were not disturbed. On the 5th the temperature was slightly subnormal and kept at 98° all day; the pulse was 104. The abdomen was not distended and there was no marked tenderness. The wound was dressed twice; there was a slight fæcal odour in the discharge, a good deal of which had escaped by the drainage-tubes in front. On the 6th the temperature in the morning was 98·6° and in the evening 97·8°; the pulse was 112. The patient was not quite so well. The abdomen was considerably distended and tympanitic, but there was no marked tenderness over the abdomen and abdominal breathing was present. There was a great tendency to nausea and once or twice there was vomiting. On the 7th the temperature was 98° in the morning and 98·8° in the evening. The distension was more marked and there was slight tenderness at the lower part of the abdomen, but nothing very noticeable. The patient vomited three or four times during the day and took food badly. Her facial expression was more of the abdominal type and the tongue was dry. There was a good deal of smell from the wound and she passed nothing at all per rectum. A rectal tube was passed beyond the region of the wound and an enema was administered with very slight results—in fact, nothing more than washing out the fæces from the rectum. On the 8th the patient was distinctly worse. The abdomen was very distended, the patient was taking hardly any food, and some vomiting occurred. The pulse was 120. There was no pain; her condition was obviously very serious. The question was evidently between peritonitis and intestinal obstruction, and as the patient was going down-hill it was clear that some investigation must be made as to which it was, although this was very reluctantly done on account of the fear of breaking down the adhesions which had already formed and the consequent risk of infecting the abdomen. The drainage-tubes were accordingly taken out and the finger was inserted into the cavity; it was found that one coil of intestine had been lying between two of the drainage-tubes and very slight

pressure of the finger, without breaking down the adhesions which had formed around, restored this coil to its proper position. Only three of the tubes were reinserted and the general peritoneal cavity was not opened into. On the 9th the patient was very much better. The bowels had acted freely twice during the night and a great deal of flatus had been passed; the distension of the abdomen was less. The vomiting and sickness were also much lessened. The discharge from the wound still had a fæcal odour. The pulse was 112 and the temperature was normal. From this date the wound healed steadily and the patient gradually improved in condition. Upon two occasions when attempts were made to leave out the tubes it was found necessary to put them back, but on the whole the discharge of pus from the wound was comparatively slight and though for a few days it had a fæcal odour this gradually passed off. As regards the discharge from the rectum, after the first three or four days there was apparently no discharge at all, and as far as one could judge no pus subsequently escaped per rectum, so that the opening must have closed or a piece or intestine must have come down over the opening and sealed it from quite an early period in the treatment of the case; the rectal opening, from which so much trouble was feared, as a matter of fact gave practically no trouble at all. The patient was allowed to get up about Feb. 20th and went out on March 6th with a sinus at the seat of the original opening, a drainage-tube being kept in; the rest of the wound was completely healed and she was allowed to walk about wearing an abdominal belt. The albumin in the urine had markedly decreased in amount. From the time of the operation, except on two occasions when the drainage was not very good, there had been no rise of temperature whatever and she entirely lost her hectic fever, night sweats, and rectal discharge. The sinus was a very long time in closing; however, it healed completely in the early part of 1896. The patient has since married and is now in excellent health, being stout and well and with no trouble at all. On examination of the mass removed it was found to be composed of tuberculous tissue containing numerous tubercles which were at parts undergoing caseation.

Remarks by Mr. WATSON CHEYNE.—Here, therefore, the source of the evil was a large tuberculous tumour, which had suppurated, and it was this chronic abscess which had been opened and which had also perforated into the rectum. As to the point of origin of this abscess one really could not come to a satisfactory conclusion; included in the mass which was removed were the remains of the ovary which was recognisable and a piece of the broad ligament, though the Fallopian tube could not be distinguished among the mass of inflammatory material. Whether the disease originated in the Fallopian tube or in connexion with the ovary or whether it originated quite outside these structures and became adherent to them it really was quite impossible to say. Against the view that it was in the first instance a tubal condition was the fact that certainly nothing like the whole tube was distended. The tube in the immediate vicinity of the uterus was perfectly healthy and I am rather inclined to think that it originated in the cellular tissue of the pelvis, probably outside the peritoneal cavity.

The great interest of the case is of course the possibility of removing a septic mass like this without infecting the peritoneal cavity and more especially the possibility of leaving an opening of considerable size communicating freely with the rectum and the peritoneum without the occurrence of any subsequent peritonitis. It seemed to me that all that could be done was to see that there was a free opening for the discharge anteriorly and to trust to the rapid shutting off of the general peritoneal cavity by the matting together of the coils around. The rectum, of course, had been very carefully washed out beforehand and it was also washed out through the opening with weak sublimate solution; therefore, one could hope that no actual solid particles of fæces would find their way into the abdominal cavity before the part was completely sealed off. And this anticipation was evidently entirely realised. Since I operated on this case records of cases have been published in which openings have been left in septic cavities in the abdomen, where the wound has been packed with gauze to absorb the discharge and also to shut off the general peritoneal cavity. This is the method which I have adopted also in cases in which I have had to do with abscess where it was not properly shut off from the abdominal cavity. But I cannot say that I like the plan any better than that of using drainage tubes; the gauze does not absorb very well and adheres firmly to the intestine, and in taking it out one may have to use considerable force and may thus run a certain risk of tearing up the young adhesions at the time when there is more infective material about than there was when the operation was performed; and in one case I have seen an accident occur in regard to the partial strangulation with gauze similar to that which happened in my case with the tube. That point is also one of great importance and interest, viz., the occurrence during the few days of symptoms in which the diagnosis between obstruction and an insidious peritonitis was difficult; and until I was quite sure that some intervention was necessary I hesitated to disturb the wound and run the risk of infecting the peritoneal cavity. Very possibly one large tube would have sufficed, but I did not like to trust to it, and this occurrence illustrates the disadvantage of using more than one tube owing to the tendency of the coils of intestines to slip in between the tubes. If I had a similar case again I should use one very large tube in the first instance. The case teaches us to bear in mind the possibility when one is draining the cavity, whether with a tube or with gauze, that distension and other symptoms which at first may lead one to think that peritonitis is setting in may be due to partial or complete constriction of the intestinal canal by the tubes.

PATHOLOGICAL SOCIETY OF LONDON.

Distribution of Leprosy Bacilli in the Tissues.—Hæmatocele in a Hydronephrotic Kidney.—Latent Tuberculosis of the Tonsil.—Hæmorrhage into the Suprarenal Capsules of Infants.—External Rupture of an Aortic Aneurysm.—Exhibition of Specimens.

A MEETING of this society was held on May 3rd, the President, Dr. J. F. PAYNE, being in the chair.

Professor KANTHACK exhibited, for Dr. BERGENGRUEN (Riga), specimens showing the Distribution of the Leprosy Bacillus in the Tissues and the Histogenesis of the Giant Cells in Leprous Lesions of the Larynx. Unna was the first to maintain that the leprosy bacilli inhabit the lymphatics and not the cells. This was denied by all except Leloir. In 1895 Dr. Bergengruen together with Gerich proved unequivocally the correctness of Unna's view Last year Herman and Dohi also confirmed Unna's view at the Leprosy Conference in Berlin, but those observers overlooked Dr. Bergengruen's previous work. The specimens prepared by the latter showed clearly that the so-called "globi" and "lepra cells" are merely cross sections of bacillary thrombi in the lymphatics. In impression specimens prepared from leprous intra-laryngeal ulcers the bacilli were found in irregular branched clusters, not inside the cells. The masses were cylindrical and evidently consisted of tubular structures. In sections the bacillary masses were arranged in delicate chains and bands, often running as parallel lines through the tissue. They generally lay in spaces lined by endothelium. They possessed no nuclei or cell outline. The "globi" and "lepra cells" represented bacillary thrombi. He had no doubt that leprosy bacilli were occasionally found in the cells also. Further, the specimens distinctly proved that the giant cells in the leprous larynx were due to endothelial proliferation around the bacillary thrombi. The latter appeared to be engulfed by the giant cells, but actually they remained in the lumen of the lymphatic vessel. The thrombus acted like a foreign body and irritated the contiguous endothelium at some parts, causing the cells to proliferate and form a plasmodial mass. Dr. Bergengruen's conclusions, he insisted, were only to be applied to the lesions which he had investigated, but in these he held that the specimens shown established his contentions.—The PRESIDENT said that he had examined several specimens of organs from cases of leprosy and till lately he had had no doubt that the bacilli were intra-cellular. But that day he had examined preparations prepared by Mr. Shattock from the skin of a case which had recently been under his care, and in this specimen the "globi" were not well seen and strings of bacilli were scattered through the section and did

not seem to be included in the cells.—Dr. HEBB said that for some years he had taught that the "lepra cells" were non-existent. In transverse sections of affected nerves the bacilli could be easily seen to lie between the fibres and away from the cells.—Dr. ANDREWES, without in the least questioning the correctness of the description of the appearances as described by Dr. Kanthack, asked if it were not possible that while in primary surface lesions the bacilli might be in the lymphatics in the internal organs they might be intracellular. In the spleen, for instance, he thought that he had seen them distinctly within the cells.—Professor KANTHACK, in reply, said that there were special difficulties in the case of the spleen in deciding whether organisms were in the cells or merely lying on them. The question could only be solved by making serial sections. But he would not be surprised at leprosy bacilli being found in the splenic cells as the spleen was the grave of almost all organisms.

Dr. J. ROSE BRADFORD showed a Hæmatocele in a Hydronephrotic Kidney. The patient, a man, forty-four years of age, was admitted into University College Hospital for delirium tremens and for hæmaturia. The hæmaturia was profuse and clots came away when the bladder was washed out. He had had several previous attacks of hæmaturia, but there was no history of renal colic. A tumour could be felt in the region of the left kidney; there were pain in the loin and frequency of micturition. He died from delirium tremens three days after admission. At the necropsy all the organs were found to be healthy except the left kidney and ureter. The ureter was dilated but the lower orifice was normal. The kidney was converted into a hydro-nephrotic sac, which was filled up by blood-clot, some of it recent and some old and laminated. Embedded in the clot was a large calculus one and a half inches in length. There was a villous condition of the pelvis in places and he thought this had been the source of the hæmorrhage. There was no evidence of growth.—Professor GREENFIELD asked if the renal veins were normal, as thrombosis might account for the hæmorrhage.—Dr. BRADFORD, in reply, said that the renal veins were not thrombosed. There was no interstitial hæmorrhage in the remains of the kidney.

Dr. HUGH WALSHAM read a paper on Latent Tuberculosis of the Tonsils the result of an investigation at the Victoria Park Chest Hospital. The inquiry was divided into two parts: 1. Examination of the tonsils and adjacent structures in patients who had died from tuberculosis. In a few cases there were signs of tubercle which appeared to be primary, being more advanced in the tonsil than it was elsewhere. In a large proportion he found evidence of tubercle in the tonsil which he thought to be secondary and to be due to auto-inoculation from the passage of sputum over it. This occurred even when the tonsils were atrophied. 2. Examination of the tonsils and adenoid vegetation removed by operation. In this case there was evidence of primary affection of the tonsils in a few cases, but as a rule the presence of tubercle bacilli could not be demonstrated.—The PRESIDENT remarked on the extreme importance of the paper. It had often been suggested that the tonsils were the point of entrance of the bacilli, but instances of definite tuberculous lesions were certainly far from common, possibly because the tonsils had great power of resistance and of destroying any invading organisms.

Dr. ANDREWES showed a specimen of Hæmorrhage into the Suprarenal Capsule taken from a female infant, fifteen months old, who died after about thirty-six hours' illness. There was a purpuric rash and some spots of commencing molluscum contagiosum. At the necropsy all the organs were found to be normal except the suprarenal capsules, which were both affected with interstitial hæmorrhage. Cultures from the suprarenal capsules, the blood, the lung, the kidney, and the spleen were negative except one from the lung the result probably of accidental contamination. The clinical features were those of an acute toxæmia, but if organisms were present they must have been species which did not grow on ordinary media or stain with ordinary reagents. A similar condition was sometimes seen in guinea-pigs after injection of diphtheria toxin. There were some points of resemblance to hæmorrhagic small-pox, but there was no case of that disease in the neighbourhood before or afterward.

Dr. G. F. STILL showed a specimen of Hæmorrhage and Acute Congestion of the Suprarenal Capsules in Infants from a child, aged fourteen months, who died from acute tuberculosis. The left suprarenal was uniformly infiltrated with extravasated blood, especially the medullary portion. The right was normal. Excluding cases in stillborn infants Dr. Still had only been able to find 18 cases in which acute congestion or hæmorrhage occurred in the suprarenals of infants. In 11 of these there was hæmorrhage and hæmorrhage occurred much more often in the right suprarenal than in the left (3 to 1). The cases were arranged in three groups: 1. Those in which death occurred within a few hours or days of birth. These form the largest group. In some of these the suprarenal hæmorrhage was the immediate cause of death, the capsule being ruptured and the blood escaping into the peritoneal cavity; the symptoms were abdominal pain and collapse. 2. Those in which the suprarenal lesion was a complication of some definite disease, usually of the respiratory tract—e.g., acute tuberculosis, broncho-pneumonia, &c. 3. Those in which after an acute illness lasting only two or three days, usually with a purpuric or bullous eruption, death occurred and the suprarenal lesion appeared to be part of the fatal disease. The etiology of the suprarenal lesion is obscure. In some cases it was certainly traumatic, in a larger number asphyxial, and in the third group almost certainly toxic. Experiments have shown that certain poisons, essence of cloves, Friedländer's bacillus, diphtheric toxin, given by the mouth or by injection, to guinea-pigs produce acute congestion or hæmorrhage in the suprarenals.

Dr. GARROD and Dr. DRYSDALE also showed a specimen of Hæmorrhage into the Suprarenal Capsule of an Infant. The patient was an unvaccinated infant, aged four months, who was brought to the hospital dead. The body, which was well nourished, was covered with a purpuric rash. No membrane was found in the pharynx and larynx and there was no ear disease. Both suprarenals were of a dark, purplish-red colour, but were not enlarged and retained their shape. On microscopical section all parts of the glands were seen to be affected, the meshes of the stroma being in places filled with red corpuscles. There can be little doubt that the disease was the same in this and in the case brought forward by Dr. Andrewes.

Dr. F. E. BATTEN showed a specimen of Hæmorrhage into the Suprarenal Capsule of a child, aged two and a half years, who was taken ill suddenly one morning with diarrhœa and vomiting, which continued during the day and following night. He was taken to the Hospital for Sick Children, Great Ormond-street, next morning, but as the onset of scarlet fever was feared he was sent home. At noon on the same day the child was again taken to the hospital as he had had a convulsion and was still convulsed. On admission the child was comatose, the temperature was 102° F., the pulse was 200, and the respiration was of the Cheyne-Stokes type in character. He had frequent convulsive attacks, the temperature rose to 106°, and the child died eight hours after admission. At the necropsy made ten hours after death, two or three small ecchymoses were found on the floor of the lateral ventricles; the lungs, heart, liver, spleen, and kidneys presented nothing abnormal. The right suprarenal body was much larger than the left and was of a dark purple colour. On microscopical section it was found that the whole suprarenal body was extremely congested with extravasation of blood into the medulla; the left suprarenal appeared to be perfectly normal.—Dr. W. S. COLMAN also mentioned a case. The patient was an infant, about ten months old, who was admitted to the Hospital for Sick Children, Great Ormond-street, in 1893, with acute fever of a day's duration and a bullous eruption which had only been present a few hours. There were a few purpuric spots. The child died about an hour after admission and a necropsy was performed a few hours later. Both suprarenal capsules were found to be affected with a diffuse interstitial hæmorrhage. The other internal organs were healthy. Cultures were made from the suprarenals, from the ventricular blood, and from the fluid in the bullæ. One colony of some cladothrix (almost certainly accidental) was found in one of the cultures from the blood, but the other cultures remained sterile. No organisms were found on staining sections of the various organs.—Dr. VOELCKER mentioned a case which he had seen at the Middlesex Hospital in a child, two years old, who was supposed to be suffering from hæmorrhagic small-pox. Hæmorrhages were found after death in both suprarenal capsules. In nearly all the cases which had been quoted there had been convulsions during the illness. The nature of these was not clear. During last year he had examined the body of a girl who had died in the Middlesex Hospital under the care of Dr. Coupland. During life she had symptoms which suggested strychnia poisoning. The only lesion discovered was advanced

caseation of both suprarenal capsules.—The PRESIDENT observed that the cases bore some resemblances to some forms of phosphorous poisoning due to the administration of small doses for some time. In these cases the onset was often sudden and hæmorrhages occurred into the internal organs, but he did not know that the suprarenal capsules were specially affected.

Dr. FREYBERGER showed a specimen of External Rupture of an Aneurysm of the ascending part of the Arch of the Aorta, taken from the body of a woman, fifty-two years of age, who died in the Great Northern Central Hospital in April, 1898. There was a history of the presence of a lump on the front of the chest for two years, but there had only been pulsation for three months. The tumour rapidly increased in size after her admission and after a week the skin which had become thinned over it cracked and blood oozed out. This oozing increased and she died from hæmorrhage in a few hours. At the necropsy the tumour in front of the chest was found to consist of firm blood-clot lying in an irregular cavity which opened into the aneurysmal sac, which passed through the second internal intercostal space, eroding the rib and cartilage to open into the ascending part of the arch of the aorta.

The following card specimens were exhibited :—

Dr. H. D. ROLLESTON : (1) Pin in the Vermiform Appendix; and (2) Round Pellets in a Dermoid Cyst.

Mr. G. B. JAMES: Primary Sarcoma of the Œsophagus.

Dr. HEBB : (1) Perigastric Cyst; and (2) Cancerous Infiltration of the Pericardium secondary to Cancer of the Œsophagus.

CLINICAL SOCIETY OF LONDON.

Transplantation of Tendon.—Bradycardia following Graves's Disease.—Congenital Heart Disease in a "Mongol" Idiot.—Acute Gangrenous Appendicitis.—Amyotrophic Lateral Sclerosis.—Hemiplegia after Typhoid Fever.—Osteitis Deformans.—Acute Epiphysitis of the Femur.—Estlander's Operation for Empyema.—Gastro-jejunostomy.

A CLINICAL meeting of this society was held on April 29th, the President, Mr. LANGTON, being in the chair.

Mr. F. S. EVE showed three cases in which he had performed the operation of Transplantation of Tendon to correct deformities due to paralysis. The operation was one which had undergone a good deal of modification since it was first devised and he followed the method of Goldthwaite. The method consisted in making a longitudinal incision into the tendon of a paralysed muscle and inserting and fixing into the incision the cut end of the tendon of a muscle which was normal. In many cases, no doubt, this merely acted as a support to a lax tendon as unless the muscle whose tendon was used came from the same group it could hardly be expected that the patient should be able to call it into action except in connexion with the muscles with which it was accustomed to act. One of the patients was a boy, aged nine years, who had paralysis of the external peronei and extensor muscles of the leg as a result of division of the external popliteal nerve, in which recovery had not followed the suture of the divided ends. He therefore divided the tendon of the posterior tibial muscle near its insertion and inserted it into the tendon of the extensor longus digitorum. He then exposed the tendo Achillis and separated a band from it and carried it above the external malleolus and inserted it into the tendon of the peroneus longus. In another case of ordinary infantile paralysis there was extreme talipes equino-varus and complete paralysis of the peroneus longus and nearly complete loss of power in the extensor longus digitorum. Mr. Eve performed an operation for lengthening of the tendo Achillis and also carried the tendon of the tibialis round and inserted its cut end into the tendon of the extensor longus digitorum. There was now hardly any talipes equinus remaining.—Mr. JACKSON CLARKE said that some years ago he had assisted Mr. Noble Smith to insert the tendon of the peroneus longus into the tendo Achillis to correct talipes calcaneus. If there were much contracture of the tendo Achillis it would be advisable to correct this before attacking the other tendons. He thought that the term "tendon re-implantation" was better than those usually employed to describe the operation.

Dr. PASTEUR showed a woman, sixty-five years of age, suffering from Exophthalmic Goitre which had been followed by Bradycardia. The symptoms of Graves's disease followed rather acutely after some gynæcological operation twenty-four years before. The symptoms at that time were typical, her pulse being from 130 to 140 per minute. She also had a goitre, exophthalmos, and tremors. At the present time the goitre had been followed by almost complete atrophy of the gland and the pulse rate had fallen to from 40 to 50 per minute. The only symptoms of Graves's disease which had persisted were the exophthalmos and the tremors. There was definite enlargement of the left ventricle and evidence of some lesion of the aortic valves, probably atheromatous in character. There were no symptoms of myxœdema except that she was extremely sensitive to cold and that her voice was a little suggestive. The heart lesion was similar to that which had been met with in other cases of bradycardia and he thought on the whole that the bradycardia was due to the cardiac lesion rather than to myxœdema.—Dr. A. MORISON was inclined to attribute the bradycardia to the shrinkage of the thyroid gland. The pulse although normally slow became much faster when the patient was excited or nervous, whereas it had been observed in the cases of bradycardia due to organic disease that these variations did not occur.—Dr. ARTHUR DAVIES discussed the occurrence of myxœdema after Graves's disease. He also mentioned several cases of Graves's disease which he had followed up which showed that the prognosis was not necessarily bad.—Dr. DE HAVILLAND HALL had lately seen a patient who had had Graves's disease twelve years ago and now had early though distinct signs of myxœdema.—Dr. PASTEUR, in reply, said that the association of myxœdema and Graves's disease could not be common. The antecedents of patients with myxœdema were always carefully gone into and yet there was hardly ever a history of previous enlargement of the thyroid gland. The possibility of myxœdema had been constantly present in his mind, but there was no definite evidence of it. The patient had been treated with small doses of aconite and with belladonna, with bromide, and later with thyroid extract. The latter did not agree, causing palpitation, and it was given up. The patient had lost weight during her illness, which did not support the idea of myxœdema, but he admitted that the nature of the case was doubtful and he hoped to report the progress at a later date.

Dr. A. E. GARROD showed a child illustrating the association of Congenital Heart Disease with the "Mongol" type of Idiocy. The case was one of a series which he had collected and intended to bring before the society at a later date. The child was sixteen months old and had the typical facies, with sloping eyes, large epicanthal fold, round forehead, large tongue, which was nearly constantly protruded and withdrawn, and had a very brachycephalic skull. In addition she was cyanosed and had marked clubbing of the fingers. There was a loud systolic murmur best heard to the left of the sternum, about the centre of the cardiac area. At this site there was also a thrill. The site of the lesion was uncertain, but it did not seem to be an ordinary case of pulmonary stenosis. Dr. Garrod had observed this association of congenital heart disease with the "Mongol" type of idiocy in seven cases. Such cases did not appear to be met with in idiot asylums, probably because they did not live till the age at which they were admitted to these institutions. There was an article by Dr. John Thomson of Edinburgh in the March number of the *Scottish Medical and Chirurgical Journal* on "Cases of Imbecility in Infancy" in which he mentioned 3 cases in which the association was present. Dr. Garrod had previously pointed out how frequently other malformations were associated with congenital heart disease and therefore the association of mental defect with these cases was interesting to him. The association of heart disease, however, with idiocy in general was rare.—Dr. G. A. SUTHERLAND said that in the last 3 years he had seen 3 cases presenting this association. In 1 which died there was a patent foramen ovale.

Mr. W. G. SPENCER showed a case of Gangrenous Appendicitis in a boy, aged thirteen years, who had had several previous attacks of abdominal pain. The onset of the symptoms in the present attack was sudden, with pain in the right iliac fossa, for which his mother administered castor oil, after which he began to vomit. On admission his temperature was 102° F. and there was acute pain and tenderness in the right iliac region at McBurnie's point. On cutting down in the usual manner he found the appendix kinked on itself and gangrenous. A drop of pus could be squeezed out of it before it was opened, showing how near it was to perforation.

It was removed and the abdominal wall was carefully sutured in layers. Recovery was uneventful. On section the appendix was found to contain a fæcal concretion. Mr. Spencer observed that in young persons appendicitis rarely led to the formation of a perityphlitic abscess, but perforation and peritonitis were rapidly brought about.

Dr. C. E. BEEVOR showed a woman, aged forty-seven years, suffering from Amyotrophic Lateral Sclerosis, who presented the phenomenon of jaw clonus. The illness had begun two years ago with bulbar symptoms and during the last few years she had developed some atrophy of the muscles of the left hand and spasticity of the lower limbs. The knee-jerks and elbow-jerks were much exaggerated and there was well-marked ankle clonus. There was also jaw clonus, a symptom to which he had drawn attention in 1881, and which with one exception he had only met with in cases of amyotrophic lateral sclerosis. The disease was one affecting the upper part of the pyramidal tract, the lower reflex centres being unaffected. Thus although voluntary power over the palate was entirely lost it contracted in a reflex manner when it was touched.—Dr. ORMEROD said that he had seen an exactly similar case in which amyotrophic lateral sclerosis began with bulbar symptoms and in which there was jaw clonus.

Dr. H. D. ROLLESTON showed a man, aged thirty years, suffering from Left Hemiplegia, which occurred on the twenty-fourth day of an attack of typhoid fever. He was a left-handed man and at the onset there was some aphasia. There were no convulsions at the onset. The fever ran a normal course and the hemiplegia had gradually improved. Dr. F. Hawkins had collected 17 cases of this kind and in all the cases in which there was a post-mortem examination there was embolism. Osler had reported 2 cases in which there was cerebral thrombosis, the arteries being affected. In his case he thought that the balance of evidence was in favour of arterial thrombosis. The absence of convulsions was against the view that this could be due to venous thrombosis, but the differential diagnosis between arterial and venous thrombosis was notoriously difficult.—Dr. HERRINGHAM mentioned a case in which hemiplegia occurred in the third week of typhoid fever. Two years later there was still some one-sided weakness and disorderly movement on effort and sometimes some athetoid movement even when the arm was at rest. As regards the question of the probability of thrombosis he mentioned that it was common in cases of typhoid fever to find minute thrombi in the renal vessels.—Dr. FRANCIS HAWKINS said that there were only 8 cases recorded in English literature and of these 4 were in children. More than half recovered and in all of those which were examined post mortem a clot was found in the middle cerebral artery.

Dr. ROLLESTON also showed, for Mr. C. T. DENT, a woman, aged fifty-two years, suffering from Osteitis Deformans. Twelve years ago she had begun to suffer from pain and swelling in the long bones in all four extremities and during the last few years this had increased. Skiagrams were shown which demonstrated considerable thickening and also bending of the bones, so that those of the forearm were seen to be curved like those of the anthropoids. It was generally supposed that most of the cases occurred in men, but out of 45 recorded cases the numbers occurring in patients of either sex appeared to be almost equal. Drug treatment had had no effect in relieving the pain.—Dr. DE HAVILLAND HALL said that in a similar case he had given the patient great relief by the administration of 5 grains of iodide of potassium combined with 2 grains of quinine.—Dr. F. PARKES WEBER mentioned a case in which he had administered iodide of potassium without benefit, but the pains at once diminished after an accident in which the patient broke his thigh.—Dr. LEONARD GUTHRIE mentioned a case in which a woman had this affection almost confined to the lower limbs and in which treatment entirely failed to relieve the pain.

Mr. WALLIS showed an infant, sixteen months old, who had suffered from Acute Epiphysitis of the Head of the Femur leading to the formation of a large abdominal abscess in which the head of the femur was found. The symptoms began acutely and after three weeks there was a large abdominal swelling. An incision was made just above Poupart's ligament and a large quantity of pus escaped. On introducing the finger the head of the femur was found attached to the hip bone by a small shred of membrane, having evidently perforated the acetabulum. Recovery was rapid and there was only ¾ in. of shortening.

Mr. SPENCER showed a young woman on whom he had performed Estlander's operation. The original empyema did not drain well, partly owing to the inaction of the left half of the diaphragm which formed a pocket. Portions of four or five ribs had been freely removed. There was now a large gap in which the pleura was covered by cicatricial skin only. Nevertheless the movements of the chest were good and there was practically no lateral curvature.

Mr. WALLIS showed a woman, over fifty years of age, suffering from Carcinoma of the Stomach, for whom he had performed the operation of gastro-jejunostomy. At the time of the operation the patient was extremely emaciated, but since then she had gained flesh and was able to take ordinary food although the growth remained. The operation was performed under the influence of local anæsthesia produced by the subcutaneous injection of a 4 per cent. solution of eucaine. This solution acted very rapidly and it was unnecessary to wait even a minute before using the knife.

SOCIETY OF ANÆSTHETISTS.

A MEETING of the above society was held on April 21st, Dr. DUDLEY BUXTON, President, being in the chair.

Mr. GRANT MORRIS read notes of the following case. The patient, a woman, aged thirty years, suffered from pain in the region of the left kidney. At the time of admission she looked cachectic and had a trace of albumin which disappeared before the day of operation. She was operated on, an exploratory abdominal section being performed. Ether was given from a Clover's inhaler, but was never pushed; the induction was normal. Towards the end of the operation some cyanosis and a good deal of secretion of frothy mucus appeared; neither was alarming in amount. After sixty-five minutes she was removed from the operating table. She was then cyanosed, the breathing was unimpeded but shallow and sighing, and her condition was thought to betoken the onset of vomiting. Conjunctival reflex was present and the pupils were equal and contracted. Fifteen minutes later she became of a ghastly ashy grey colour, respiration ceased and with it the pulse. Artificial respiration was performed, a large quantity of frothy watery secretion coming away. The necropsy showed the lungs to be full of frothy secretion. Death apparently resulted from failure of respiration due to acute œdema of the lungs set up by the ether.—In answer to the PRESIDENT it was stated that no hæmorrhage into the medulla had occurred.—Dr. SILK had met with a somewhat similar case in which, owing to a large quantity of ether being inhaled, acute œdema had caused waterlogging of the lungs. Artificial respiration in these cases, he opined, did harm.—Dr. STARLING thought the condition of the kidneys might be a factor in producing the acute œdema. He instanced a case supporting his view.—Mr. DAVIS had met with a case in which giving ether to a patient with Bright's disease had been followed by hæmaturia and death in twenty-four hours.

Dr. SILK narrated a case of a patient, aged sixty-five years, in whom after a very brief administration of the A.C.E. mixture (fifteen minutes) jaundice and albuminuria had developed. She had been in hospital eight days and appeared to be free from renal or hepatic disease and in fairly good health. The operation was simply the incision of a mammary tumour causing no shock. Two days after the administration albuminuria was noticed and in a week bile was found in the urine, which persisted for six days. The albuminuria was present for two days longer. Ultimately both disappeared. — Miss ALDRICH-BLAKE had met with severe albuminuria in a child, aged eight years, following a brief administration of chloroform. The condition appeared twenty-four hours after the inhalation and persisted for four days.

Mr. MACCARDIE narrated an instance of Albuminuria following Ether.—The PRESIDENT pointed out that milder forms of jaundice and "biliary upset" were not unfrequent sequelæ of taking anæsthetics, especially in the case of chloroform. With regard to albuminuria recent statistics showed that that condition was more frequent after chloroform inhalation than after ether provided the kidneys were sound.

Mr. CHAPMAN (Tunbridge Wells) communicated the notes of a case of Death following the Exhibition of Chloroform.

Mr. HORACE PECHELL read a paper on Ether Administration. He pointed out the various methods in use and then described the method which he advocated. An Ormsby

inhaler of special construction was used. Two ounces of ether were poured into the bag and the sponge was replaced. The valve was left open but gradually closed and then the ether from the bag becomes inhaled. The administrator then gently tilts the bag, thus wetting the sponge with ether. As toleration is effected more and more ether is allowed to soak the sponge. In giving gas before ether he allows nitrous oxide to be inhaled for 30 seconds and then applies the Ormsby inhaler in the manner described above. Mr. Pechell advocates the semi-recumbent posture for etherisation in dental operations.—Mr. CARTER BRAINE described his method of giving gas and ether. He had tried Mr. Pechell's plan but had found that it destroyed the bag. He exhibited an inhaler which was a modified form of Ormsby's instrument, being adapted for the exhibition of ether, of chloroform, or of the A.C.E. mixture. It was capable of complete sterilisation.—Dr. SILK thought that Mr. Pechell's method was not free from objection. The view that any form of etherisation ought to, or was expected to, produce lividity and cyanosis was, he contended, quite wrong. The posture referred to was commonly adopted amongst anæsthetists.—Mr. BELLAMY GARDNER thought that the amount of ether employed was excessive and that some would probably fall on the patient's face.—The PRESIDENT was surprised that Mr. Pechell had omitted to mention Mr. Clover's method, which was, he thought, superior to all those he had described. No cyanosis or lividity followed its use when the method was understood and properly carried out. It was the only method whereby an unbroken nitrous oxide and ether anæsthesia could be obtained.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Detail in Surgery.—Method of Exposing the Kidney without Division of Muscles, &c.—Recurrent Hæmorrhage from the Ear.—Deciduoma Malignum.—Xerostomia.—Exhibition of Cases and Specimens.

A MEETING of this society was held on April 22nd, the President, Dr. J. BRAITHWAITE, being in the chair.

Mr. PRIDGIN TEALE read a paper on Detail in Surgery, illustrated by operations for hæmorrhoids, which will be found on page 1244 of our present issue.

Mr. MAYO ROBSON read a paper on a Method of Exposing the Kidney without Division of Muscles, Vessels, or Nerves.

Mr. W. H. BROWN read notes of a case of Recurrent Hæmorrhages from the Ear. The patient, a child aged five years, suffered from follicular tonsillitis followed by otitis media and otorrhœa. There was little pain and only slight rise of temperature. Two weeks later, without any obvious cause, free arterial hæmorrhage took place from the right ear, about a pint of blood being lost. The ear was packed with gauze and a compress for four days and a few hours after this was removed a second violent hæmorrhage occurred. A swelling bulging into the soft palate and pushing inwards the tonsil was now noticed and believing that the source of hæmorrhage was the internal carotid artery Mr. Brown ligatured this vessel. No further bleeding took place and the child ultimately quite recovered.

Dr. HELLIER showed the Uterus and Appendages from a case presenting the symptoms and appearances characteristic of the condition called Deciduoma Malignum, also drawings of the recent specimen and microscopic sections of the primary and metastatic growths. He also showed by the lantern photographic reproductions of the drawings published by Sänger in his original paper and by Nové Josserand and Lacroix and others. The patient, aged thirty-nine years, died twenty weeks after an apparently normal confinement. Her main symptoms were continuous hæmorrhage and fœtid discharge. Death resulted from septic pneumonia. There was malignant growth in the fundus uteri, broad ligament, and ovaries, perforation of the uterus and rectum, and secondary growths in the peritoneum and lungs

Dr. SHARP (Whitby) read notes of a case of Xerostomia (Mouth Dryness), which was published in THE LANCET of April 23rd.

The following cases, pathological specimens, &c., were exhibited :—

Dr. CHURTON : (1) A case of Addison's Disease ; and (2) Cases from the Wards of the Leeds Infirmary.

Dr. TREVELYAN : (1) Anomalous case of Congenital Cardiac Disease ; (2) specimens from a case of Cerebral Abscess ; (3) specimens illustrating the Anatomy of the Cerebral Ventricles ; and (4) specimen of Enlarged Thymus the probable cause of sudden death.

Mr. LITTLEWOOD : (1) Case of Actinomycosis in a child, with microscope specimens ; (2) boy who was impaled on a stake ; (3) Gall-stones from a case of Cholecystotomy ; (4) Fibro-cystic Tumour of the Uterus removed by Abdominal Hysterectomy ; and (5) Malignant Disease of the Penis.

Dr. MANTLE (Halifax) : Case of Progressive Muscular Atrophy.

Dr. CHADWICK : Two cases of Pseudo-hypertrophic Paralysis—(1) Hypertrophy with Paralysis ; and (2) Atrophy with Contraction.

Dr. CHADWICK and Mr. W. H. BROWN : Specimens from a case of Hydronephrosis (R) with Congenital Cystic Degeneration (L).

Mr. W. H. BROWN : (1) Vermiform Appendix recently removed for Recurrent Inflammation ; (2) Hydrocele of the Canal of Nuck ; (3) case of Removal of the Jaw for Malignant Epulis ; (4) Multiple Keloid ; and (5) Lumbar Colotomy six years after operation.

LIVERPOOL MEDICAL INSTITUTION.

The Acidity of the Urine.—Non-diphtheritic Membranous Sore-throat.—Exhibition of Cases, &c.

A MEETING of this society was held on April 28th, the President, Dr. MACVIE CAMPBELL, being in the chair.

A collection of recent radiographs by Mr. THURSTAN HOLLAND and Nine Photographs of Surgical Disease by Mr. THELWALL THOMAS were exhibited.

Dr. T. R. BRADSHAW read a note on the Acidity of the Urine. He showed that litmus could not be employed as the indicator in the estimation of acidity of the urine, because solutions which contained salts of phosphoric acid were never neutral to litmus ; if they were not distinctly acid or alkaline they were amphoteric. He advocated the employment of phenol-phthalein as an indicator and maintained that the objections which had been urged against it were not valid. His observations led him to differ from the teaching of Bence Jones and Sir Wm. Roberts, who held that the acidity of the urine was diminished after a meal. He found from the averages drawn from 160 estimations of the acidity of the urine of a healthy man that the acidity followed a fairly regular curve : high during sleep, it fell rapidly after "getting up," and remained at a minimum until about noon, after which it rose steadily and reached a maximum about 9 P.M. He found that the absolute amount of acid excreted varied nearly on the same lines as the relative acidity and, further, that it varied inversely as the volume of urine. The latter was a remarkable circumstance which was unconsciously acted upon by the physician when he gave alkalies to promote diuresis.

Mr. S. KELLETT SMITH read a note on the Dum-Dum Bullet.—Mr. BANKS, Mr. WESTBY and Dr. PERMEWAN spoke.

Dr. J. R. THOMPSON read notes of a case of Non-Diphtheritic Membranous Sore-throat. The illness began with hoarseness and redness of the left posterior pillar of the fauces ; on the third day a thin white membranous exudation appeared, covering the left tonsil and left side of the pharynx accompanied by marked malaise and pain in the throat without swelling of the tonsil or lymphadenitis. On the fourth day the membrane was thicker and greyish, and on removal of a portion for examination the mucous membrane bled slightly but was not eroded. The membrane re-formed to some extent. There was an attack of syncope on the fifth day. The temperature ranged between 99° and 102° F. for three days and then became normal. There was no albuminuria and no paralysis. Convalescence was tedious. Bacteriological examination on the fifth day showed a rod-like bacillus, shorter and thicker than the Löffler bacillus, and no cocci, while on the seventh day it showed a bacillus longer than the Löffler bacillus and a net culture of streptococci.—Dr. C. A. HILL thought that the case was one of streptococcal infection, and pointed out that all cases of membranous sore throat were not necessarily due to the diphtheria bacillus.—The PRESIDENT, Dr. WARRINGTON, Dr. LOGAN, and Dr. PETER DAVIDSON spoke.

Mr. RUSHTON PARKER showed a man, thirty-eight years of age, on whom he had performed Amputation at the Hip-joint

for Recurrent Tumour of the Femur. In June, 1895, the patient was admitted into the Royal Infirmary for constant pain in the right hip of some nine months' duration. The diagnosis lay between ostitis and tumour of bone, but in the absence of definite swelling at first that of ostitis was made. A small soft swelling eventually appeared and an incision over the hip-joint was made and a myeloid sarcoma was removed from the head and neck of the femur. The wound healed, all pain disappeared, and for a time a useful limb resulted. Towards the end of 1896 the patient fell in the street and was taken to the Royal Southern Hospital, where he was under the care of Dr. Alexander, who attempted to remove the growth which had recurred. This not proving practicable amputation was proposed. For this purpose the patient placed himself again under the care of Mr. Parker, who amputated at the hip-joint. He is now in good health and apparently free from disease.

Mr. BANKS showed a woman from whom he had removed a portion of a Parenchymatous Goitre and gave a lantern demonstration of Illustrations of Ancient and Modern Surgery.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Diseases of the Nose.

A MEETING of this society was held on April 20th, Dr. CATTLE, the President, being in the chair.

Mr. MACKIE read a paper on Diseases of the Accessory Sinuses of the Nose. After alluding to their anatomical features attention was more particularly directed to suppuration occurring in the maxillary sinus, which he believed to be a more common disease than was generally supposed, fourteen cases having come under his observation in the last fifteen months. Catarrh of the mucous membrane with stenosis of the ostium accounted for the majority, and though cases of dental origin were not infrequent they were less important and quickly recovered after the extraction of a tooth. The distinguishing signs of the disease were pointed out and the value of transillumination as an aid to diagnosis was demonstrated on a patient. In the treatment of recent cases frequent irrigation by a catheter passed through the ostium sufficed to effect a cure; but when the disease was of long duration it was necessary to drill a hole through the canine fossa, subsequently enlarging it with a chisel, and at the same time making a counter opening into the lower meatus of the nose, the cavity being packed with iodoform gauze and treated with an astringent douche. In suppuration of the ethmoid sinuses surgical interference was both difficult and dangerous, but when the employment of a warm nasal douche failed to give relief it was necessary to puncture the bulging ethmoid bone.

Dr. CATTLE, Mr. WILLIS, Mr. COX, and Dr. TRESIDDER took part in the discussion which followed.

TYPHOID FEVER AT EXETER.—At the meeting of the Exeter city council held on April 27th Dr. G. T. Clapp, the medical officer of health of No. 2 district, Exeter, reported that 7 cases of typhoid fever with 1 death had occurred in that division. Most of the patients had partaken of milk supplied by a dairy where the water used for washing the milk cans had, on being submitted to bacteriological examination, showed contamination by animal refuse. The objectionable source of supply had now been closed.

CONGRESS OF HYDROLOGY, CLIMATOLOGY, AND GEOLOGY.—The fifth International Congress of Hydrology, Climatology, and Geology will be held at Liège from Sept. 25th to Oct. 3rd, this city being selected on account of its proximity to the principal Belgian mineral springs (Spa, Chaudfontaine, &c.), rendering it easy for members to visit those localities. Other excursions will include various places of interest, such as Verviers (with especial reference to the reservoir for water-supply), to the seaside bathing establishments at Ostend and other coast towns, and to Aix-la-Chapelle. Applications for membership should be sent before May 15th to the general secretary, Dr. G. Jorissenne, 130, Boulevard de la Sauvenière, Liège, together with a remittance of 20 francs (16*s.*) for members and 10 francs (8*s.*) for wives of members or university students. The northern railway companies of France and Belgium have promised a reduction of 50 per cent. in the fares.

Reviews and Notices of Books.

The Peritoneum. By BYRON ROBINSON, B S., M.D. Chicago, Illinois. Part I. Histology and Physiology. With 247 Illustrations. Chicago: C. V. Waite and Co. Pp. 400. 1897. Price $3·75.

THESE are indeed the days of monographs. The handsomely got-up, well-illustrated, and portly volume before us labelled "The Peritoneum" deals only with the histology and physiology of that important membrane. There are still the anatomy, the pathology, and the symptomatology and treatment of its diseases to come, that is, if the promise held out in the preface, "that it is intended to publish in each volume as much bibliography as can be selected from the literature on the peritoneum," be any indication of the future progress of the work. The bibliography appended to this volume is portentous and must have taken much time and research to complete. It extends over 103 pages with upwards of 50 references on each page, making a total of nearly 6000. There can be no doubt in regard to the value of such work, for it greatly facilitates the labours of all those who are engaged in the same line of research and is a good example of what will have to be done for each organ if the immense number of facts which have been observed and recorded in journals are not to be buried in total oblivion. The peritoneum is as a rule rather curtly dismissed by anatomical writers, who of course busy themselves chiefly with its folds and attachments, and still more so by the physiologists, by whom it is merged in their account of serous membranes generally, whilst by the histologists the several elements, as endothelium, lymphatics, nerves, and vessels, are described under separate sections, and it is therefore difficult to state what space is accorded to it; but taking the treatises at hand, such as those of Blandin, Cruveilhier, Quain and Sharpey, Testut, Sappey, Hyrtl, Krause, Aeby, and Poirier amongst the anatomists, and those of Toldt, Stricker, Kölliker, Renaut, Satterthwaite, and Piersol amongst the histologists, we should think about from ten to twenty pages is the limit assigned to it. The appearance of a large work exclusively devoted to it is therefore welcome, especially when written by an original worker, since it is frequently the subject of disease and is almost as frequently exposed to mechanical injury in the course of surgical operations.

There is abundant evidence that the author has taken great interest in his work and that the study of the peritoneum has been to him a labour of love. He has made many original drawings and has treated each constituent of the membrane with great minuteness. In this prolixity is the defect of the volume. It would have been twice as valuable if it had been reduced to half the size. We are continually inclined to say with Falstaff, "Oh, thou hast damnable iteration." The work commences with a historical sketch, which is succeeded by chapters devoted to the membrane as a whole and to its separate elements—as the endothelium, the subperitoneal tissue, the blood-vessels, the lymphatics and nerves, the physiology, and the methods of preparation and examination—and closes with a chapter giving a *résumé* of the whole subject. The author describes in much detail the endothelial cells, or flattened cells with sinuous borders which form the membrane proper, with the stomata at the angles and the pseudo-stomata between the sides or applied margins of the cells. He particularly insists on the double character of the inter-endothelial line and shows that if examined with high powers a space, the inter-endothelial space, lies between the contiguous borders of adjoining cells and that this space is crossed by numerous protoplasmic processes

connecting the cells with each other; it is, he contends, through and along these spaces that leucocytes migrate. He believes the stomata spuria to be actually connective tissue corpuscles or their processes projecting upwards between the endothelial plates.

The stomata vera he entertains no doubt are the apertures of vertical canals which open, on the one hand, into the peritoneal cavity and, on the other, into the subperitoneal lymph spaces; they are in many instances lined by germinal granular polyhedral nucleated cells, whilst others are destitute of these cells. The active processes of absorption take place through both the stomata vera and the inter-endothelial spaces as well as through the blood-vessels, the former openings being particularly numerous in the peritoneum investing the tendinous centre of the diaphragm, where absorption is known to be rapid both for fluids and for solid particles. The peritoneum, owing to the number of leucocytes it possesses, has a limited power of resisting septic germs. The subperitoneal tissue with its blood-vessels and nerves are decribed at great length.

A long and important chapter is devoted to a description of the subperitoneal tissue, a subject which is usually very lightly passed over. Dr. Robinson, with Henle, limits the peritoneum proper to the single layer of endothelial cells which covers the opposed surfaces of the sac. The subperitoneal tissue includes a membrana limitans, fibrous tissue, elastic tissue, areolar tissue, fixed and migratory tissue corpuscles, various kinds of cells, such as vacuolated, branched, fibrillated nerve and fat cells, together with nuclei,—each of these receives a due share of attention. The white fibrous tissue is composed of long wavy bundles and presents two forms; one of these, the reticulated, appears in the omentum. It is liable to atrophy and exhibits holes, due to an atrophic process, which is not well understood, but which, Dr. Robinson has observed, may commence at the age of two years in the human subject. Each bundle is entirely invested with a layer of endothelial cells. The other form consists of parallel wavy bundles arranged in planes. These elements of the tissue can be well seen when freshly mounted in glycerine. The second element is the elastic, the fibres of which are straight and unite with each other in a reticulated manner, the closeness of the network varying much in different parts and in different animals. It is very abundant in the rabbit and in the human subject, in the subserous tissue of the ligamentum latum and in the parts adjacent to the bladder, for obvious reasons. Dr. Robinson describes three forms and alludes to a fourth—Henle's fenestrated membrane. The several forms of the various kinds of cells are fully considered and the accounts of each are illustrated by good drawings which are quite original. The importance of the easily separable planes of the subperitoneal connective tissue in promoting the spread of pus from one region to another is particularly emphasised. Dr. Robinson finds three forms of nerve fibre in the peritoneum—viz., medullated nerves, non-medullated nucleated axis cylinders, and fibres of Remak; the last-named he describes as consisting of a striated, fibrillated nerve axis and a nucleated neurolemma with a probable trace of medullary sheath, and as closely resembling irregular bundles of connective tissue.

Dr. Robinson's style of writing does not recommend itself to us. It is somewhat disjointed, giving to the reader the impression that the casual thoughts of the author have been jotted down as they occurred to him and then strung together to form a paragraph. Passages like the following are frequent: "Pathologic processes make the peritoneum manifest in exudation as in ascites, which experimentation of injecting fluid into the peritoneum makes its absorptive power manifest" (p. 290); "which," we presume, is a misprint for "while"; but even admitting this the sentence runs badly and is barely intelligible. What is to be said of this sentence: "It appears from my experiments that the leucocyte is possessed of wonderful malleability of plasticity of adjustability" (p. 186). Perhaps the two "of's" should be two "or's." Then the correction of the press has been very carelessly done. Here (p. 5), for example, is a quotation under the head of Johann Friedrich Meckel in which that anatomist's work is quoted as "Nova Experimenta et Observationes de Finibres Venosum ac Vasorum Lymphaticorum in Ductus Niscerague Excretoria Corporum ejusque Structuræ utilitate." Dr. Robinson has a curious mode of twisting a sentence so that it looks like a translation from the German with the verb at the end. For example, speaking of the relations of the blood capillaries to the lymphatics, he says (p. 211): "In the interstitial spaces, especially in the amphibia as is noticed in the cut presented, on the turtle the blood capillaries are embedded." No cut, or reference to a cut, is appended. The errors of the press are, indeed, almost innumerable. To mention only a few of the many we have noticed "splinter" is printed for "sphincter" and "diaphram" for "diaphragm." Then, again, we have the "ligamentum peritonei" instead of "ligamenta peritonei," p. 161; "unstripped muscles" for "unstriated," p. 170; "branches" for "branched"; "vacuolation" for "vacuolated," p. 200; "cilibre" for "calibre"; "flummerzellen" for flimmerzelle," p. 251. Pflueger may be right or wrong, but Pflüger spells his name in the latter mode, as anyone who refers to Pflüger's "Archiv" is well aware. "Nucleus" for "muscle," p. 263; "one stomata vera" for "one stoma verum," p. 247; "stomata acts" instead of "stomata act"; "wells" for "walls," p. 271; "laminæ" for "lamina," p. 272; "swelling" for "swellings," p. 273; and "the" for "a"; "*Journ. de la Anat. de la Phys.*" for "*Journ. de l'Anat. et de la Physiologie*," p. 285; "guarded" for "guard," p. 291. The index again is very unsatisfactory, the references being arranged without the least attention to the order of sequence of the letters, so that Ptolemy precedes Peritoneum, Purkinje Paladino, and Rudolph Radiation—in fact, the references are thrown in anyhow, necessitating the perusal of every item under each initial letter to discover any particular reference. Even the word "Peritoneum," which might be expected to be correctly indexed, is split up into three parts, whereof the first gives 5 references, the second 16, and the third 15, each entry being separated by other headings. In like manner there are five distinct headings of "Endothelia," all of which should have been grouped under one. Notwithstanding these blemishes, which will no doubt be removed when another edition is called for, the work will prove serviceable to histologists and physiologists as an epitome of the present state of our knowledge of this extensive and important membrane, and there can be no doubt that in these days of laparotomy, hysterectomy, and other formidable operations, the details both of the anatomy and physiology of the peritoneum should be familiar to every surgeon.

Researches on Tuberculosis: The Weber-Parkes Prize Essay, 1897. By ARTHUR RANSOME, M.D., M.A. Cantab., F.R.S. London: Smith, Elder, and Co. 1898. Price 2*s.* 6*d.* net.

THE subject chosen for the essay in the first triennial competition for the prize founded by Dr. Hermann Weber for bestowal by the Royal College of Physicians of London was as follows: "The Means, Prophylactic or Curative, deemed by the Author to have Value in the Control of Tuberculosis, especial regard being had to their application to Human Tuberculosis." The successful essay is now published and it cannot be said to ignore any of the issues of this far-reaching subject. Hence perhaps its somewhat condensed form and didactic expression, but it teems with information and contains many original observations. In order to give some idea of the

scope of the essay it will suffice to enumerate the chief departments into which the author has divided his subject, each one of which could well be expanded into an essay of equal length with that which here treats of them all. These divisions are:—(*a*) the Past and Present Prevalence of Tuberculosis in this Country and its Fatality—where it is shown how regularly and almost uniformly has been the fall in the death-rate from this disease during the past half century. (*b*) The Distribution of the Disease in Nations and in Local Areas—which proves clearly that density of population is a prime factor in its prevalence. (*c*) The Natural History of the Bacillus of Tubercle, its Nature, its Habits, Forms, Products, Degrees of Virulence, and the Influence of External Conditions upon its Growth and Infective Power. This section contains several very interesting inquiries undertaken by the author as to the conditions favourable to the development of the bacillus outside the body, especially the influence of organically charged vapours when removed from the air and light. (*d*) Bodily Predisposition, Natural or Acquired. It is of interest here to find Dr. Ransome expressing a strong doubt as to the alleged close relationship between pleurisy with effusion and tuberculosis. (*e*) The Channels and Sources of Infection. In this chapter is ably summarised the existing knowledge of the modes of tuberculous infection, the commonest of course being the inhalation of dried tuberculous dust; next, that of the ingestion of infected food, as well also of "dust" from the atmosphere; next, inoculation through the skin; rarer still, direct infection by the generative organs; and, he adds, significantly, "direct infection from the breath of phthisical persons is probably the rarest of all." Two cases of "mixed infection" in which anti-streptococcic serum was injected without avail are related. (*f*) The Conditions and Limits of the Power of Infection form the next heading, whilst the final section deals with Preventive and Prophylactic Measures and also with the Dietetic and Medical Treatment of the Disease. Thus the subject is completely surveyed and with much skill, so that the essay constitutes a valuable contribution to literature which cannot fail to be consulted by all subsequent students of this universal malady.

The Tallerman Treatment by Superheated Dry Air: Case Notes and Medical Reports, with numerous Illustrations. Edited by ARTHUR SHADWELL, M.A., M.B. Oxon., M.R.C.P. Lond. London: Baillière, Tindall, and Cox. 8vo, pp. xii. and 173. 63 Plates. 1898. Price 3*s.* 6*d.* net.

MANY endeavours have from time to time been made to utilise high temperatures in the treatment of disease, and in several instances a certain measure of success has followed these attempts; but the temperature attained by these methods has never reached any very great height and, in fact, in no case has it approached the boiling point of water. The failure we now know was due to the fact that the heat was applied either by means of steam or, if dry air were at first used, it became very quickly saturated with moisture by the increased perspiration of the part treated, so that practically steam was applied in this way also. Now, it is not possible for any of the tissues of the human body to endure watery vapour at a temperature at all near the boiling point of water, though if the heat is applied by means of air which is perfectly dry far higher temperatures can be borne, but the difficulty consists in maintaining the dryness of the air in spite of the greatly increased evaporation from the surface of the body. It is in the solution of this difficulty that the merit of Mr. Tallerman's invention chiefly consists; he has devised an apparatus by which the air is kept really dry and in this way a limb or a part of a limb may be exposed to temperatures varying from 200° to 300° F. without any discomfort. The local effects of the high temperature are to dilate all the cutaneous blood-vessels, to stimulate the circulation of the part, and to relieve pain. The general effects are to dilate the superficial vessels, to increase the pulse-rate and the force of the heart's action, and to raise temporarily the general temperature of the body. This increase of temperature may amount to two or even to three degrees Fahrenheit. So far we have considered only the means by which these high temperatures have been rendered possible and their physiological results. The therapeutic value of the method remains to be dealt with. The method is undoubtedly of value in several forms of joint disease, especially in chronic rheumatism and rheumatoid arthritis which are so little amenable to ordinary treatment, and in this book many cases are recorded in which other diseases, such as peripheral neuritis, chronic ulcers, and flat-foot have been benefited. The treatment has been employed fairly extensively, but is certainly deserving of being more widely known. Of course, it is not a panacea and time will enable us to distinguish what cases are likely to derive benefit from it. The power of relieving pain is sometimes very great, and the increased freedom of movement in chronic joint disease is equally remarkable. The book contains notes of a large number of cases in which the apparatus has been employed and in many instances photographs are given of the patients before and after treatment. Mr. Tallerman is to be greatly commended in that he has not endeavoured to bring his invention before the public but has confined its employment to the members of the medical profession. We feel sure that before long the Tallerman method of applying air at high temperatures to diseased portions of the body will take the place it deserves in the estimation of medical men as the most satisfactory method at their disposal of treating many hitherto very intractable morbid conditions.

A Catechism of Palmistry. By IDA ELLIS. London: George Redway. Pp. 155. Plates, 19. 1898. Price 2*s.* 6*d.*

PALMISTRY has become a fashionable amusement for "at homes," &c.; and for those who wish to amuse their friends by telling them what they wish to hear or to annoy others by endowing them with characteristics the reverse of pleasant a good deal of information will be found in this volume. It is written entirely in the form of question and answer, which makes it easy of reference but not pleasant to read. Regarded, however, as a "scientific" work, as it pretends to be—"the sciences of chirognomy and chiromancy explained"—it is simply absurd. Scraps of truth are mixed up with ridiculous ignorance. The following is an example: Q. "What is the cause of lines being produced in the palm of the hand?" A. "Its extreme sensitiveness, for in the hand the nerves are far more numerous than in any other part of the body except the tongue, and in the palm the nerves are more in number than in any other part of the hand; this accounts for the very keen sense of touch which the palm possesses and it also accounts for the readiness of the palm to register the internal heat of the body, for in a fever the hand becomes very hot though the rest of the body may be cold. There are proofs that the nervous fluid from the brain acts directly upon the hand," &c. The writer would have been wiser to confine herself to a description of the "lines of the hand" and their supposed significance than to talk such nonsense about physiology. Our readers may know whether or not they have mistaken their profession by the following question and answer: "What is the appearance of a successful doctor's hand?" "The mount of Mercury should be full and three clear, upright lines upon it, the line of Fortune clearly traced, the mount of Moon well developed to show love of discovery, and for a surgeon the hand should also be rather hard and the fingers square or spatulate."

LIBRARY TABLE.

Lehmann's Medicinische Hand-Atlanten. Band VI., Zweite Ausgabe. *Atlas der Syphilis und der Venerischen Krankheiten.* Von Professor Dr. FRANZ MRACEK. München: J. F. Lehmann. (*Lehmann's Medical Handy Atlases.* Vol. VI. Second edition. *Atlas of Syphilis and Venereal Diseases.* By Professor F. MRACEK. Munich: J. F. Lehmann.) 1898. Price 14*s.*—The series of manuals which is being issued by the firm of J. F. Lehmann of Munich has already received a favour which has been thoroughly well deserved. More than one of these handy atlases have been issued in a second edition and as five additional volumes are announced to be in preparation, giving a total of twenty-two, it will be seen that the ground covered by them is considerable. Each volume contains a large number of coloured plates and in several there are also additional figures in the text, but the text is here subordinate to the main purpose of the book, which is that of an atlas. The present volume constitutes a fairly compendious and useful guide to the lesions of syphilis in its various stages, there being no fewer than seventy-one plates. Most of these are well executed and characteristic, their value being enhanced by the appended descriptions giving the clinical history of each case from which the drawing was made.

Le Phénomène de l'Agglutination des Microbes et ses Applications à la Pathologie. Par le Dr. RAOUL BENSAUDE. (*The Phenomenon of Agglutination of Microbes and its Applications to Pathology.* By Dr. R. BENSAUDE.) Paris: G. Carré et C. Naud. 1897.—That a monograph of nearly 300 pages could be based upon the single fact of microbic "agglutination" bears eloquent testimony to the extent to which bacteriology at present holds the field. The work is not merely historical; it is also well furnished with personal observations by the author, Dr. Bensaude. The infective diseases in which this property of blood serum has been established are of considerable number and its application to diagnosis has been employed in several. It is, however, in typhoid fever that it is most reliable. In the majority of cases the reaction can be obtained early in the disease; in a few it may not appear until defervescence or later, when, of course, its clinical utility is small. Dr. Bensaude, whilst stating that a negative result of the test does not necessarily exclude typhoid fever, considers that it yet affords strong probability against it, and he particularly mentions that the test has been of undoubted value in the early diagnosis of typhoid fever from the typhoid condition that may accompany other disorders, such as tuberculosis and influenza.

Recent Materia Medica. By F. HARWOOD LESCHER, F.C.S., Pereira Medallist, &c. Fifth edition. London: J. & A. Churchill. Pp. 219. 1897.—This is a useful volume for reference, containing as it does all the drugs and preparations recently introduced and also a description of "drugs occasionally prescribed." A considerable quantity of new matter has been introduced into this edition. Modern chemical synthesis has given us many new drugs and bacteriological investigations have produced serum cultures and antitoxins, whilst physiological research has furnished many organic animal extracts. The work is very well brought out and the type is good and clear. Under each preparation will be found its chemical formula (when known), its synonyms, its physical properties, its therapeutical properties, and the dosage.

JOURNALS AND REVIEWS.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S. London: J. and A. Churchill. 1898. Vol. XLI. Part I. Price 10*s.*—This part contains five memoirs which are: 1. The Habits and Structure of Arenicola Marina, by F. W. Gamble, M.Sc., and J. H. Ashworth, B.Sc., of Owens College, Manchester, with five plates. Although this animal has been well described by various observers the carefully and accurately drawn up description given by Mr. Gamble and Mr. Ashworth is not the less acceptable. They find that there are two forms or varieties, one of which is the "lug" or common shore lugworm, whilst the other is found on the Lancashire coast—at least, at the upper part of the Laminarian zone—and is large and better-developed than the former. They constitute the scavengers of the sands and the authors of the article quote from Mr. Davison who finds that on Holy Island sands the entire layer of sand to a depth of two feet passes once in twenty-two months through the bodies of the lugworms which live in it, and that in a year the average volume of sand per acre which is brought to the surface in the form of castings is 1911 tons. The drawings which accompany this memoir are very carefully made from dissections. 2. The Aseptic Cultivation of Mycetozoa, by Caspar O. Miller, M.D., with two plates. The forms of the mycetozoa which are here dealt with are physarum cinereum and stemonitis and illustrations are given of the spores of Chondrioderma and Ceratium porioides. 3. On the Development of Tubulipora and on some British and Northern Species of this Genus, by Sidney F. Harmer, Sc.D. It is here shown that a process of embryonic fission is of normal occurrence in Cyclostomatous Polyzoa; with two plates. The memoir treats of the structure of the colony and of the ovicell; the history of the species and genus; the diagnosis of the species; the nature of certain vesicles found in the tentacles; an account of the development; and, finally, the morphology of the internal parts of the ovicell. 4. The Molluska of the Great African Lakes, by J. E. S. Moore. The author finds that there are twenty-four genera. Lake Nyassa, which is about 340 miles in length, and from 20 to 40 miles across, is of unknown depth, no bottom being found through a great part of its area, with soundings of 300 fathoms. The coast is swept in many parts with a heavy surf and the molluscan portion of the population thins out quickly beyond 100 feet of depth. Many parts are uninhabited. Lake Tanganyika is much shallower and thirteen genera were found. 5. In a second memoir, Mr. Moore gives the Anatomy of the Typhobias with a description of the new genus Bathanalia, with two plates.

The Journal of Anatomy and Physiology. Conducted by Professor Sir WILLIAM TURNER, Professor D. J. CUNNINGHAM, Professor A. MACALISTER, Professor J. G. M'KENDRICK, and Professor G. D. THANE. Vol. XXXII. Part III. 1898. London: Charles Griffin. Price 6*s.*—The articles contained in this part are both numerous and valuable. They are as follows. 1. Sir William Turner, F.R.S.: An Account of a Decorated Sculptured Human Skull from New Guinea. The form of the skull was hyperdolichocephalic, its length-breadth index was very low, not exceeding 68. The sculpture was a rude resemblance to the human face carved on the frontal bone. 2. Richard Assheton, M.A.: An account of a Blastodermic Vesicle of the Sheep of the Seventh Day with Twin Germinal Areas, with a plate. 3. Sir William Turner, F.R.S.: Moderator Band in Left Ventricle and Tricuspid left Auriculo-ventricular Valve. 4. Gordon Sharp, M.D. Edin.: Spontaneous Cure and Torsion of Aneurysm in a Sheep. 5. D. A. Welsh, M.A., M.D. Edin.: Concerning the Parathyroid Glands: a critical, anatomical and experimental study, with a plate. The importance of these glands is shown by the serious or fatal results which follow their complete ablation. 6. N. Bishop Harman, B.A., M.B.: The Caudal Limit of the Lumbar Visceral Efferent Nerves in Man. This he finds to be at the level of the twenty-second spinal nerve, which is usually the second lumbar. Many drawings accompany and illustrate his article and show that much labour has been spent on the requisite dissections. 7. Wakelin Barratt, M.D. Lond: On the Anatomical Structure

of the Vagus Nerve, with five plates. The plates show the appearances presented by sections of the vagus at different heights. 8. F. G. Parsons, F.R.C.S.Eng.: The Muscles of Mammals with Special Relation to Human Myology. This article is the first lecture of a course of lectures delivered at the Royal College of Surgeons of England. 9. Arthur Keith, M.D. Aberd.: A Preliminary Investigation of the Influence of Body Posture on the Position and Shape of Abdominal and Thoracic Organs—an interesting article, which contains many details that are of importance to the clinical observer. 10. A. Birmingham, M.D. R.U.I.: The Shape and Position of the Bladder in the Child. 11. R. Tait Mackenzie, B.A., M.D.: Natural Selection as Shown in the Typical Speed Skater—a very instructive article, showing the influence of special kinds of exercise on thews and sinews. 12. R. Broom, M.D. Glasg.: On the Arterial Arches and Great Veins in the Fœtal Marsupial. 13. Edward J. Bles, B.Sc.: The Correlated Distribution of Abdominal Pores and Nephrostomes in Fishes. 14. Walter H. Gaskell, M.D. Cantab.: On the Origin of Vertebrates deduced from the Study of Ammocœtes, with a plate. In this article Dr. Gaskell supplies a large amount of additional evidence in favour of his view of the origin of vertebrata from arthropods through the larval form of the lamprey. 15. A. M. Paterson, M.D. Edin.: The Genito-urinary Organs of the Female Indian Elephant, with two plates. 16. Alfred Young, M.B. Edin., and Arthur Robinson, M.D. Edin.: On the Development and Morphology of the Vascular System in Mammals, the Posterior End of the Aorta and the Iliac Arteries. In an editorial note it is stated that the editors intend to effect certain improvements, especially in the matter of illustration, and they earnestly desire that the journal may be placed on the list of books to be purchased by many public libraries in universities and other scientific institutions which are at present non-subscribers. The value of the communications made to this journal render such a request quite reasonable and legitimate and it is to be hoped that the librarians and library committees will see that the proposal is carried out.

Scottish Medical and Surgical Journal.—In a lengthy paper on the Occurrence of a Non-allantoic or Vitelline Placenta in the Human Subject Dr. J. W. Ballantyne (Edinburgh) gives an illustrated description of a sireniform fœtus—i.e., one in which the legs and feet are fused in a single lower limb. Dr. G. Halley (Dundee) writes on Perforating Ulcers of the Foot; and Dr. R. O. Adamson (Glasgow) on the Symptoms of Perforated Gastric Ulcer. Dr. Alexander Johnston (Methven) contributes a short report of two cases of Puerperal Fever treated with anti-streptococcus serum. There are four other original communications.

Edinburgh Medical Journal.—The opening paper is a Clinical Lecture on Pleural Effusion, by Dr. T. Lauder Brunton. Dr. G. A. Sutherland describes four cases of Fragilitas Ossium Scorbutica in Young Children; the pathology of the disease is that scorbutic extravasation of blood under the peritoneum leads to its detachment from the bone. Dr. A. Logan Turner writes on the Illumination of the Air Sinuses of the Skull. He used a five-candle electric lamp mounted on a tongue depressor and inserted in the mouth. If the person under examination closes his eyes the perception of light may become obvious to him in one or both of them. Altogether there are eight original articles.

Dublin Journal of Medical Science.—The titles and authors of the original communications are as follows: Recurrent Idiopathic Pneumothorax, by Dr. J. Magee Finny; a Study in the Surgery of Joints, by Mr. J. S. McArdle; the Housing of the Poor in Dublin, by Dr. H. C. Tweedy; and the first portion of the Clinical Report of the Rotunda Lying-in Hospital for Three Years, from Oct. 1st, 1893, to Oct. 1st, 1896, by Dr. W. J. Smyly. During this period 4006 women were confined in the hospital, with 14 deaths, and 8273 were confined at their own homes.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE ordinary Comitia of the College was held on April 28th, the President, Sir SAMUEL WILKS, Bart., being in the chair.

The following gentlemen were admitted to the Membership of the College: E. G. E. Arnold, M.B. Durh., G. B. Hunt, M.D. Lond., W. Lamb, M.D. Edin., E. Playfair, M.B Lond., and H. B. Shaw, M.D. Lond.

Licences were granted to the 93 candidates who had passed the recent examinations.

A letter was read from the family of the late Sir Richard Quain thanking the College for their sympathy.

A letter was read from Dr. G. V. Poore offering for the acceptance of the College a manuscript copy of the letter-book of Dr. Thomas Wharton, comprising letters to his son when at college in 1673, the transcript having been made by permission of Mr. Wharton, M.P.—Dr. GEE, the Senior Censor, moved a vote of thanks to Dr. Poore, and in seconding the motion Dr. PAYNE remarked that he had had an opportunity of reading the letters which threw an important light on the condition of the medical profession at that period.

A communication from the secretary of the Royal College of Surgeons of England was read reporting the proceedings of its Council.

A communication from the General Medical Council was read calling attention to the results of a competition in November last for appointments in the Medical Service of the Navy and to deficiencies shown in general education.

Communications were read concerning the subject of legislation for midwives from the secretary to the "Midwives Bill Committee" and from the secretary of the British Medical Association, who forwarded a copy of a proposed "Midwifery Nurses Bill" with an explanatory statement and memorandum. These communications were referred to the committee of the College appointed to deal with this question, the members of which were nominated by the President as follows: Sir W. Priestley, M.P., Dr. Playfair, Dr. Champneys, Dr. Black, Sir R. Douglas Powell, Dr. Dickinson, Dr. F. Taylor, and Dr. Duffin.

Dr. Poore and Dr. Corfield were nominated delegates to the Congress of the Sanitary Institute at Birmingham in September.

A communication from the Dean of the medical school of Guy's Hospital was read conveying a resolution adopted by a meeting of teachers to the effect that it is undesirable for any changes to be made in the regulations of the first examination without previous consultation with examiners and teachers. It was explained by the President and the Registrar that this was the course which was followed when any changes were in contemplation.

The ballot was then taken for the election of Fellows and the following Members proposed by the Council were declared elected and will be admitted at the next meeting of the College: William Richard Huggard, M.D. R.U.I., Switzerland; Oswald Auchinleck Browne, M.D. Cantab.; Charles Joseph Arkle, M.D. Lond.; Joseph Wiglesworth, M.D. Lond., Prescot; William Bramwell Ransom, M.D. Lond., Nottingham; Frederick Parkes Weber, M.D. Cantab.; Harry Johnstone Campbell, M.D. Lond., Bradford; Horace George Turney, M.D. Oxon.; George Redmayne Murray, M.D. Cantab., Newcastle-on-Tyne; Arthur Newsholme, M.D. Lond., Brighton; Benjamin Arthur Whitelegge, M.D. Lond.; and John Francis Walkingame Tatham, M.D. Dub.

Dr. NORMAN MOORE presented two reports from the Committee of Management dated March 7th and April 1st and moved their adoption, reserving recommendation No. 4 in the first report for separate consideration. The reports with that exception being adopted Dr. Moore next proposed the adoption of the clause in question. In this section of their report the committee point out that although students were encouraged to complete their studies in chemistry, physics, practical chemistry and biology before entrance on the professional course proper, and although certain institutions had been recognised as suitable places of instruction in these subjects, there was little gained by the student, who was still required by the regulations to go through a course of five years at a medical school, no matter whether he had been registered previously or not. In the case of students who enter at a recognised medical school

immediately after passing their preliminary examination the five years of study commence to count at once, although the first of those years may be spent solely in receiving instruction in chemistry, physics, practical chemistry, and biology.
